Passthrough-read enables the FPolicy server (functioning as the hierarchical storage management (HSM) server) to provide read access to offline files without having to recall the file from the secondary storage system to the primary storage system.

When an FPolicy server is configured to provide HSM to files residing on a SMB server, policy-based file

migration occurs where the files are stored offline on secondary storage and only a stub file remains on primary storage. Even though a stub file appears as a normal file to clients, it is actually a sparse file that is the same size of the original file. The sparse file has the SMB offline bit set and points to the actual file that has been migrated to secondary storage.

Typically when a read request for an offline file is received, the requested content must be recalled back to primary storage and then accessed through primary storage. The need to recall data back to primary storage has several undesirable effects. Among the undesirable effects is the increased latency to client requests caused by the need to recall the content before responding to the request and the increased space consumption needed for recalled files on the primary storage.

FPolicy passthrough-read allows the HSM server (the FPolicy server) to provide read access to migrated, offline files without having to recall the file from the secondary storage system to the primary storage system. Instead of recalling the files back to primary storage, read requests can be serviced directly from secondary storage.

Copy Offload (ODX) is not supported with FPolicy passthrough-read operation.

Passthrough-read enhances usability by providing the following benefits:

- Read requests can be serviced even if the primary storage does not have sufficient space to recall requested data back to primary storage.
- Better capacity and performance management when a surge of data recall might occur, such as if a script or a backup solution needs to access many offline files.
- Read requests for offline files in Snapshot copies can be serviced.

Because Snapshot copies are read-only, the FPolicy server cannot restore the original file if the stub file is located in a Snapshot copy. Using passthrough-read eliminates this problem.

- Policies can be set up that control when read requests are serviced through access to the file on secondary storage and when the offline file should be recalled to primary storage.

For example, a policy can be created on the HSM server that specifies the number of times the offline file can be accessed in a specified period of time before the file is migrated back to primary storage. This type of policy avoids recalling files that are rarely accessed.

== How read requests are managed when FPolicy passthrough-read is enabled

You should understand how read requests are managed when FPolicy passthrough-read is enabled so that you can optimally configure connectivity between the storage virtual machine (SVM) and the FPolicy servers.

When FPolicy passthrough-read is enabled and the SVM receives a request for an offline file, FPolicy sends a notification to the FPolicy server (HSM server) through the standard connection channel.

After receiving the notification, the FPolicy server reads the data from the file path sent in the notification and sends the requested data to the SVM through the passthrough-read privileged data connection that is established between the SVM and the FPolicy server.

After the data is sent, the FPolicy server then responds to the read request as an ALLOW or DENY. Based on whether the read request is allowed or denied, ONTAP either sends the requested information or sends an error message to the client.

= Requirements, considerations, and best practices for configuring FPolicy

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.authentication/..media/

Before you create and configure FPolicy configurations on your SVMs, you need to be aware of certain requirements, considerations, and best practices for configuring FPolicy.

FPolicy features are configured either through the command line interface (CLI) or through APIs.

== Requirements for setting up FPolicy

Before you configure and enable FPolicy on your storage virtual machine (SVM), you need to be aware of certain requirements.

- All nodes in the cluster must be running a version of ONTAP that supports FPolicy.

- If you are not using the ONTAP native FPolicy engine, you must have external FPolicy servers (FPolicy servers) installed.
- The FPolicy servers must be installed on a server accessible from the data LIFs of the SVM where FPolicy policies are enabled.

Beginning with ONTAP 9.8, ONTAP provides a client LIF service for outbound FPolicy connections with the addition of the `data-fpolicy-client` service. [Learn more about LIFs and service policies](#).

- The IP address of the FPolicy server must be configured as a primary or secondary server in the FPolicy policy external engine configuration.
- If the FPolicy servers access data over a privileged data channel, the following additional requirements must be met:

- SMB must be licensed on the cluster.

Privileged data access is accomplished using SMB connections.

- A user credential must be configured for accessing files over the privileged data channel.
- The FPolicy server must run under the credentials configured in the FPolicy configuration.
- All data LIFs used to communicate with the FPolicy servers must be configured to have `cifs` as one of the allowed protocols.

This includes the LIFs used for passthrough-read connections.

== Best practices and recommendations when setting up FPolicy

When setting up FPolicy on storage virtual machines (SVMs), you need to be familiar with configuration best practices and recommendations to ensure that your FPolicy configuration provides robust monitoring performance and results that meet your requirements.

- External FPolicy servers (FPolicy servers) should be placed in close proximity to the cluster with high-bandwidth connectivity to provide minimal latency and high-bandwidth connectivity.
- The FPolicy external engine should be configured with more than one FPolicy server to provide resiliency and high availability of FPolicy server notification processing, especially if policies are configured for synchronous screening.
- It is recommended that you disable the FPolicy policy before making any configuration changes.

For example, if you want to add or modify an IP address in the FPolicy external engine configured for the enabled policy, you should first disable the policy.

- The cluster node-to-FPolicy server ratio should be optimized to ensure that FPolicy servers are not overloaded, which can introduce latencies when the SVM responds to client requests.

The optimal ratio depends on the application for which the FPolicy server is being used.

== Passthrough-read upgrade and revert considerations

There are certain upgrade and revert considerations that you must know about before upgrading to an ONTAP release that supports passthrough-read or before reverting to a release that does not support passthrough-read.

== Upgrading

After all nodes are upgraded to a version of ONTAP that supports FPolicy passthrough-read, the cluster is capable of using the passthrough-read functionality; however, passthrough-read is disabled by default on existing FPolicy configurations. To use passthrough-read on existing FPolicy configurations, you must disable the FPolicy policy and modify the configuration, and then reenable the configuration.

== Reverting

Before reverting to a version of ONTAP that does not support FPolicy passthrough-read, the following conditions must be met:

- All the policies using passthrough-read must be disabled, and then the affected configurations must be modified so that they do not use passthrough-read.
- FPolicy functionality must be disabled on the cluster by disabling every FPolicy policy on the cluster.

= What the steps for setting up an FPolicy configuration are

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./authentication../media/

Before FPolicy can monitor file access, an FPolicy configuration must be created and enabled on the storage virtual machine (SVM) for which FPolicy services are required.

The steps for setting up and enabling an FPolicy configuration on the SVM are as follows:

1. Create an FPolicy external engine.

The FPolicy external engine identifies the external FPolicy servers (FPolicy servers) that are associated with a specific FPolicy configuration. If the internal “native” FPolicy engine is used to create a native file-blocking configuration, you do not need to create an FPolicy external engine.

2. Create an FPolicy event.

An FPolicy event describes what the FPolicy policy should monitor. Events consist of the protocols and file operations to monitor, and can contain a list of filters. Events use filters to narrow the list of monitored events for which the FPolicy external engine must send notifications. Events also specify whether the policy monitors volume operations.

3. Create an FPolicy policy.

The FPolicy policy is responsible for associating, with the appropriate scope, the set of events that need to be monitored and for which of the monitored events notifications must be sent to the designated FPolicy server (or to the native engine if no FPolicy servers are configured). The policy also defines whether the FPolicy server is allowed privileged access to the data for which it receives notifications. An FPolicy server needs privileged access if the server needs to access the data. Typical use cases where privileged access is needed include file blocking, quota management, and hierarchical storage management. The policy is where you specify whether the configuration for this policy uses an FPolicy server or the internal “native” FPolicy server.

A policy specifies whether screening is mandatory. If screening is mandatory and all FPolicy servers are down or no response is received from the FPolicy servers within a defined timeout period, then file access is denied.

A policy's boundaries are the SVM. A policy cannot apply to more than one SVM. However, a specific SVM can have multiple FPolicy policies, each with the same or different combination of scope, event, and external server configurations.

4. Configure the policy scope.

The FPolicy scope determines which volumes, shares, or export-policies the policy acts on or excludes from monitoring. A scope also determines which file extensions should be included or excluded from FPolicy monitoring.

Exclude lists take precedence over include lists.

1. Enable the FPolicy policy.

When the policy is enabled, the control channels and, optionally, the privileged data channels are connected. The FPolicy process on the nodes on which the SVM participates begin monitoring file and folder access and, for events that match configured criteria, sends notifications to the FPolicy servers (or to the native engine if no FPolicy servers are configured).

If the policy uses native file blocking, an external engine is not configured or associated with the policy.

= Plan the FPolicy configuration

= Plan the FPolicy external engine configuration

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./authentication../media/

Before you configure the FPolicy external engine (external engine), you must understand what it means to create an external engine and which configuration parameters are available. This information helps you to determine which values to set for each parameter.

== Information that is defined when creating the FPolicy external engine

The external engine configuration defines the information that FPolicy needs to make and manage connections to the external FPolicy servers (FPolicy servers), including the following information:

- SVM name
- Engine name
- The IP addresses of the primary and secondary FPolicy servers and the TCP port number to use when making the connection to the FPolicy servers
- Whether the engine type is asynchronous or synchronous
- How to authenticate the connection between the node and the FPolicy server

If you choose to configure mutual SSL authentication, then you must also configure parameters that provide SSL certificate information.

- How to manage the connection using various advanced privilege settings

This includes parameters that define such things as timeout values, retry values, keep-alive values, maximum request values, sent and receive buffer size values, and session timeout values.

The `vserver fpolicy policy external-engine create` command is used to create an FPolicy external engine.

== What the basic external engine parameters are

You can use the following table of basic FPolicy configuration parameters to help you plan your configuration:

Type of information	Option
---------------------	--------

SVM	<code>-vserver vserver_name</code>
<p>Specifies the SVM name that you want to associate with this external engine.</p> <p>Each FPolicy configuration is defined within a single SVM. The external engine, policy event, policy scope, and policy that combine together to create an FPolicy policy configuration must all be associated with the same SVM.</p>	

The name should be up to 200 characters long if configuring the external engine name in a MetroCluster or SVM disaster recovery configuration.

The name can contain any combination of the following ASCII-range characters:

- a through z
- A through Z
- 0 through 9
- “_”, “-”, and “.”

a|

-engine-name engine_name

a|

Primary FPolicy servers

Specifies the primary FPolicy servers to which the node sends notifications for a given FPolicy policy. The value is specified as a comma-delimited list of IP addresses.

If more than one primary server IP address is specified, every node on which the SVM participates creates a control connection to every specified primary FPolicy server at the time the policy is enabled. If you configure multiple primary FPolicy servers, notifications are sent to the FPolicy servers in a round-robin fashion.

If the external engine is used in a MetroCluster or SVM disaster recovery configuration, you should specify the IP addresses of the FPolicy servers at the source site as primary servers. The IP addresses of the FPolicy servers at the destination site should be specified as secondary servers.

a|

-primary-servers IP_address,...

a|

Port number

Specifies the port number of the FPolicy service.

a|

-port integer

a|

Secondary FPolicy servers

Specifies the secondary FPolicy servers to which to send file access events for a given FPolicy policy. The value is specified as a comma-delimited list of IP addresses.

Secondary servers are used only when none of the primary servers are reachable. Connections to secondary servers are established when the policy is enabled, but notifications are sent to secondary servers only if none of the primary servers are reachable. If you configure multiple secondary servers, notifications are sent to the FPolicy servers in a round-robin fashion.

a|

-secondary-servers IP_address,...

a|

External engine type

Specifies whether the external engine operates in synchronous or asynchronous mode. By default, FPolicy operates in synchronous mode.

When set to `synchronous`, file request processing sends a notification to the FPolicy server, but then does not continue until after receiving a response from the FPolicy server. At that point, request flow either continues or processing results in denial, depending on whether the response from the FPolicy server permits the requested action.

When set to `asynchronous`, file request processing sends a notification to the FPolicy server, and then continues.

a|

`-extern-engine-type external_engine_type` The value for this parameter can be one of the following:

- `synchronous`
- `asynchronous`

a|

SSL option for communication with FPolicy server

Specifies the SSL option for communication with the FPolicy server. This is a required parameter. You can choose one of the options based on the following information:

- When set to `no-auth`, no authentication takes place.

The communication link is established over TCP.

- When set to `server-auth`, the SVM authenticates the FPolicy server using SSL server authentication.
- When set to `mutual-auth`, mutual authentication takes place between the SVM and the FPolicy server; the SVM authenticates the FPolicy server, and the FPolicy server authenticates the SVM.

If you choose to configure mutual SSL authentication, then you must also configure the `-certificate-common-name`, `-certificate-serial`, and `-certifcate-ca` parameters.

a|

`-ssl-option {no-auth|server-auth|mutual-auth}`

a|

Certificate FQDN or custom common name

Specifies the certificate name used if SSL authentication between the SVM and the FPolicy server is configured. You can specify the certificate name as an FQDN or as a custom common name.

If you specify `mutual-auth` for the `-ssl-option` parameter, you must specify a value for the `-certificate-common-name` parameter.

a|

`-certificate-common-name text`

a|

Certificate serial number

Specifies the serial number of the certificate used for authentication if SSL authentication between the SVM and the FPolicy server is configured.

If you specify `mutual-auth` for the `-ssl-option` parameter, you must specify a value for the `-certificate-serial` parameter.

a|
-certificate-serial text
a|
Certificate authority

Specifies the CA name of the certificate used for authentication if SSL authentication between the SVM and the FPolicy server is configured.

If you specify `mutual-auth` for the `-ssl-option` parameter, you must specify a value for the `-certificate-ca` parameter.

a|
-certificate-ca text

== What the advanced external engine options are

You can use the following table of advanced FPolicy configuration parameters as you plan whether to customize your configuration with advanced parameters. You use these parameters to modify communication behavior between the cluster nodes and the FPolicy servers:

[cols="70,30"]

h| Type of information h| Option

a|
Timeout for canceling a request

Specifies the time interval in hours (h), minutes (m), or seconds (s) that the node waits for a response from the FPolicy server.

If the timeout interval passes, the node sends a cancel request to the FPolicy server. The node then sends the notification to an alternate FPolicy server. This timeout helps in handling an FPolicy server that is not responding, which can improve SMB/NFS client response. Also, canceling requests after a timeout period can help in releasing system resources because the notification request is moved from a down/bad FPolicy server to an alternate FPolicy server.

The range for this value is 0 through 100. If the value is set to 0, the option is disabled and cancel request messages are not sent to the FPolicy server. The default is 20s.

a|
-reqs-cancel-timeout integer[h|m|s]
a|
Timeout for aborting a request

Specifies the timeout in hours (h), minutes (m), or seconds (s) for aborting a request.

The range for this value is 0 through 200.

a|
-reqs-abort-timeout ``integer[h|m|s]
a|

Interval for sending status requests

Specifies the interval in hours (h), minutes (m), or seconds (s) after which a status request is sent to the FPolicy server.

The range for this value is 0 through 50. If the value is set to 0, the option is disabled and status request messages are not sent to the FPolicy server. The default is 10s.

a|
-status-req-interval integer[h|m|s]

a|
Maximum outstanding requests on the FPolicy server

Specifies the maximum number of outstanding requests that can be queued on the FPolicy server.

The range for this value is 1 through 10000. The default is 500.

a|
-max-server-reqs integer
a|

Timeout for disconnecting a nonresponsive FPolicy server

Specifies the time interval in hours (h), minutes (m), or seconds (s) after which the connection to the FPolicy server is terminated.

The connection is terminated after the timeout period only if the FPolicy server's queue contains the maximum allowed requests and no response is received within the timeout period. The maximum allowed number of requests is either 50 (the default) or the number specified by the max-server-reqs-parameter.

The range for this value is 1 through 100. The default is 60s.

a|
-server-progress-timeout integer[h|m|s]

a|
Interval for sending keep-alive messages to the FPolicy server

Specifies the time interval in hours (h), minutes (m), or seconds (s) at which keep-alive messages are sent to the FPolicy server.

Keep-alive messages detect half-open connections.

The range for this value is 10 through 600. If the value is set to 0, the option is disabled and keep-alive messages are prevented from being sent to the FPolicy servers. The default is 120s.

a|
-keep-alive-interval- integer[h|m|s]

a|
Maximum reconnect attempts

Specifies the maximum number of times the SVM attempts to reconnect to the FPolicy server after the connection has been broken.

The range for this value is 0 through 20. The default is 5.

```
a|
-max-connection-retries integer
a|
Receive buffer size
```

Specifies the receive buffer size of the connected socket for the FPolicy server.

The default value is set to 256 kilobytes (Kb). When the value is set to 0, the size of the receive buffer is set to a value defined by the system.

For example, if the default receive buffer size of the socket is 65536 bytes, by setting the tunable value to 0, the socket buffer size is set to 65536 bytes. You can use any non-default value to set the size (in bytes) of the receive buffer.

```
a|
-recv-buffer-size integer
a|
Send buffer size
```

Specifies the send buffer size of the connected socket for the FPolicy server.

The default value is set to 256 kilobytes (Kb). When the value is set to 0, the size of the send buffer is set to a value defined by the system.

For example, if the default send buffer size of the socket is set to 65536 bytes, by setting the tunable value to 0, the socket buffer size is set to 65536 bytes. You can use any non-default value to set the size (in bytes) of the send buffer.

```
a|
-send-buffer-size integer
a|
Timeout for purging a session ID during reconnection
```

Specifies the interval in hours (h), minutes (m), or seconds (s) after which a new session ID is sent to the FPolicy server during reconnection attempts.

If the connection between the storage controller and the FPolicy server is terminated and reconnection is made within the -session-timeout interval, the old session ID is sent to FPolicy server so that it can send responses for old notifications.

The default value is set to 10 seconds.

```
a|
-session-timeout [integerh][integerm][integers]
```

:leveloffset: +1

= Additional information about configuring FPolicy external engines to use SSL authenticated connections

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.authentication/../media/

[.lead]

You need to know some additional information if you want to configure the FPolicy external engine to use SSL when connecting to FPolicy servers.

== SSL server authentication

If you choose to configure the FPolicy external engine for SSL server authentication, before creating the external engine, you must install the public certificate of the certificate authority (CA) that signed the FPolicy server certificate.

== Mutual authentication

If you configure FPolicy external engines to use SSL mutual authentication when connecting storage virtual machine (SVM) data LIFs to external FPolicy servers, before creating the external engine, you must install the public certificate of the CA that signed the FPolicy server certificate along with the public certificate and key file for authentication of the SVM. You must not delete this certificate while any FPolicy policies are using the installed certificate.

If the certificate is deleted while FPolicy is using it for mutual authentication when connecting to an external FPolicy server, you cannot reenable a disabled FPolicy policy that uses that certificate. The FPolicy policy cannot be reenabled in this situation even if a new certificate with the same settings is created and installed on the SVM.

If the certificate has been deleted, you need to install a new certificate, create new FPolicy external engines that use the new certificate, and associate the new external engines with the FPolicy policy that you want to reenable by modifying the FPolicy policy.

== Install certificates for SSL

The public certificate of the CA that is used to sign the FPolicy server certificate is installed by using the security certificate install command with the -type parameter set to client-ca. The private key and public certificate required for authentication of the SVM is installed by using the security certificate install command with the -type parameter set to server.

= Certificates do not replicate in SVM disaster recovery relationships with a non-ID-preserve configuration

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.authentication/../media/

h| Configuration h| Permitted?

a|

MetroCluster or SVM disaster recovery and a cluster-scoped FPolicy external engine with no authentication (SSL is not configured)

a|

Yes

a|

MetroCluster or SVM disaster recovery and a cluster-scoped FPolicy external engine with SSL server or SSL mutual authentication

a|

No

* If a cluster-scoped FPolicy external engine with SSL authentication exists and you want to create a MetroCluster or SVM disaster recovery configuration, you must modify this external engine to use no authentication or remove the external engine before you can create the MetroCluster or SVM disaster recovery configuration.

* If the MetroCluster or SVM disaster recovery configuration already exists, ONTAP prevents you from creating a cluster-scoped FPolicy external engine with SSL authentication.

= Complete the FPolicy external engine configuration worksheet

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.authentication/..media/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.authentication/../media/

[.lead]

Before you configure FPolicy events, you must understand what it means to create an FPolicy event. You must determine which protocols you want the event to monitor, which events to monitor, and which event filters to use. This information helps you plan the values that you want to set.

== What it means to create an FPolicy event

Creating the FPolicy event means defining information that the FPolicy process needs to determine what file access operations to monitor and for which of the monitored events notifications should be sent to the external FPolicy server. The FPolicy event configuration defines the following configuration information:

* Storage virtual machine (SVM) name

* Event name

* Which protocols to monitor

+

FPolicy can monitor SMB, NFSv3, and NFSv4 file access operations.

* Which file operations to monitor

+

Not all file operations are valid for each protocol.

* Which file filters to configure

+

Only certain combinations of file operations and filters are valid. Each protocol has its own set of supported combinations.

* Whether to monitor volume mount and unmount operations

[NOTE]

There is a dependency with three of the parameters (-protocol, -file-operations, -filters). The following combinations are valid for the three parameters:

- You can specify the -protocol and -file-operations parameters.
- You can specify all three of the parameters.
- You can specify none of the parameters.

== What the FPolicy event configuration contains

You can use the following list of available FPolicy event configuration parameters to help you plan your configuration:

Type of information	Option
<p>SVM</p> <p>Specifies the SVM name that you want to associate with this FPolicy event.</p> <p>Each FPolicy configuration is defined within a single SVM. The external engine, policy event, policy scope, and policy that combine together to create an FPolicy policy configuration must all be associated with the same SVM.</p>	<code>-vserver vserver_name</code>

The name should be up to 200 characters long if configuring the event in a MetroCluster or SVM disaster recovery configuration.

The name can contain any combination of the following ASCII-range characters:

- a through z
- A through Z
- 0 through 9
- “_”, “-”, and “.”

a|
-event-name event_name
a|
Protocol

Specifies which protocol to configure for the FPolicy event. The list for `-protocol` can include one of the following values:

- cifs
- nfsv3
- nfsv4

If you specify `-protocol`, then you must specify a valid value in the `-file-operations` parameter. As the protocol version changes, the valid values might change.

```
a|
-protocol protocol
a|
File operations
```

Specifies the list of file operations for the FPolicy event.

The event checks the operations specified in this list from all client requests using the protocol specified in the `-protocol` parameter. You can list one or more file operations by using a comma-delimited list. The list for `-file-operations` can include one or more of the following values:

- `close` for file close operations
- `create` for file create operations
- `create-dir` for directory create operations
- `delete` for file delete operations
- `delete_dir` for directory delete operations
- `getattr` for get attribute operations
- `link` for link operations
- `lookup` for lookup operations
- `open` for file open operations
- `read` for file read operations
- `write` for file write operations
- `rename` for file rename operations
- `rename_dir` for directory rename operations
- `setattr` for set attribute operations
- `symlink` for symbolic link operations

If you specify `-file-operations`, then you must specify a valid protocol in the `-protocol` parameter.

```
a|
-file-operations file_operations, ...
a|
Filters
```

Specifies the list of filters for a given file operation for the specified protocol. The values in the `-filters` parameter are used to filter client requests. The list can include one or more of the following:

If you specify the `-filters` parameter, then you must also specify valid values for the `-file-operations` and `-protocol` parameters.

- `monitor-ads` option to filter the client request for alternate data stream.
- `close-with-modification` option to filter the client request for close with modification.
- `close-without-modification` option to filter the client request for close without modification.
- `first-read` option to filter the client request for first read.
- `first-write` option to filter the client request for first write.
- `offline-bit` option to filter the client request for offline bit set.

Setting this filter results in the FPolicy server receiving notification only when offline files are accessed.

- `open-with-delete-intent` option to filter the client request for open with delete intent.

Setting this filter results in the FPolicy server receiving notification only when an attempt is made to open a file with the intent to delete it. This is used by file systems when the `FILE_DELETE_ON_CLOSE` flag is specified.

- `open-with-write-intent` option to filter client request for open with write intent.

Setting this filter results in the FPolicy server receiving notification only when an attempt is made to open a file with the intent to write something in it.

- `write-with-size-change` option to filter the client request for write with size change.

`a|`

`-filters filter, ...`

`a|`

Filters continued

- `setattr-with-owner-change` option to filter the client setattr requests for changing owner of a file or a directory.
- `setattr-with-group-change` option to filter the client setattr requests for changing the group of a file or a directory.
- `setattr-with-sacl-change` option to filter the client setattr requests for changing the SACL on a file or a directory.

This filter is available only for the SMB and NFSv4 protocols.

- `setattr-with-dacl-change` option to filter the client setattr requests for changing the DACL on a file or a directory.

This filter is available only for the SMB and NFSv4 protocols.

- `setattr-with-modify-time-change` option to filter the client setattr requests for changing the modification time of a file or a directory.
- `setattr-with-access-time-change` option to filter the client setattr requests for changing the access time of a file or a directory.
- `setattr-with-creation-time-change` option to filter the client setattr requests for changing the creation time of a file or a directory.

This option is available only for the SMB protocol.

- `setattr-with-mode-change` option to filter the client setattr requests for changing the mode bits on a file or a directory.
- `setattr-with-size-change` option to filter the client setattr requests for changing the size of a file.
- `setattr-with-allocation-size-change` option to filter the client setattr requests for changing the allocation size of a file.

This option is available only for the SMB protocol.

- `exclude-directory` option to filter the client requests for directory operations.

When this filter is specified, the directory operations are not monitored.

```
a|
-filters filter, ...
a|
Is volume operation required
```

Specifies whether monitoring is required for volume mount and unmount operations. The default is `false`.

```
a|
-volume-operation {true\false}

-filters filter, ...
a|
FPolicy access denied notifications
```

Beginning with ONTAP 9.13.1, users can receive notifications for failed file operations due to lack of permissions. These notifications are valuable for security, ransomware protection, and governance. Notifications will be generated for file operation failed due to lack of permission, which includes:

- Failures due to NTFS permissions.
- Failures due to Unix mode bits.
- Failures due to NFSv4 ACLs.

```
a|
-monitor-fileop-failure {true\false}
```

= Supported file operation and filter combinations that FPolicy can monitor for SMB

[.lead]

Before you configure the FPolicy policy, you must understand which parameters are required when creating the policy as well as why you might want to configure certain optional parameters. This information helps you to determine which values to set for each parameter.

When creating an FPolicy policy you associate the policy with the following:

- * The storage virtual machine (SVM)
- * One or more FPolicy events
- * An FPolicy external engine

You can also configure several optional policy settings.

== What the FPolicy policy configuration contains

You can use the following list of available FPolicy policy required and optional parameters to help you plan your configuration:

[cols="40,20,20,20"]

Type of information	Option	Required	Default
a	SVM name		
a	-vserver vserver_name		
a	Yes		
a	None		
a	Policy name		

The name should be up to 200 characters long if configuring the policy in a MetroCluster or SVM disaster recovery configuration.

The name can contain any combination of the following ASCII-range characters:

- a through z
- A through Z
- 0 through 9
- “_”, “-”, and “.”

```
a|
-policy-name policy_name
a|
Yes
a|
None
a|
Event names
```

Specifies a comma-delimited list of events to associate with the FPolicy policy.

- You can associate more than one event to a policy.
- An event is specific to a protocol.
- You can use a single policy to monitor file access events for more than one protocol by creating an event for each protocol that you want the policy to monitor, and then associating the events to the policy.
- The events must already exist.

```
a|
-events event_name, ...
a|
Yes
a|
None
a|
External engine name
```

Specifies the name of the external engine to associate with the FPolicy policy.

- An external engine contains information required by the node to send notifications to an FPolicy server.
- You can configure FPolicy to use the ONTAP native external engine for simple file blocking or to use an external engine that is configured to use external FPolicy servers (FPolicy servers) for more sophisticated file blocking and file management.
- If you want to use the native external engine, you can either not specify a value for this parameter or you can specify `native` as the value.
- If you want to use FPolicy servers, the configuration for the external engine must already exist.

```
a|
-engine engine_name
a|
Yes (unless the policy uses the internal ONTAP native engine)
```

```
a|
native
a|
Is mandatory screening required
```

Specifies whether mandatory file access screening is required.

- The mandatory screening setting determines what action is taken on a file access event in a case when all primary and secondary servers are down or no response is received from the FPolicy servers within a given timeout period.
- When set to `true`, file access events are denied.
- When set to `false`, file access events are allowed.

```
a|
-is-mandatory {true\|false}
a|
No
a|
true
a|
Allow privileged access
```

Specifies whether you want the FPolicy server to have privileged access to the monitored files and folders by using a privileged data connection.

If configured, FPolicy servers can access files from the root of the SVM containing the monitored data using the privileged data connection.

For privileged data access, SMB must be licensed on the cluster and all the data LIFs used to connect to the FPolicy servers must be configured to have `cifs` as one of the allowed protocols.

If you want to configure the policy to allow privileged access, you must also specify the user name for the account that you want the FPolicy server to use for privileged access.

```
a|
-allow-privileged-access {yes\|no}
a|
No (unless passthrough-read is enabled)
a|
no
a|
Privileged user name
```

Specifies the user name of the account the FPolicy servers use for privileged data access.

- The value for this parameter should use the “domain\user name” format.
- If `-allow-privileged-access` is set to `no`, any value set for this parameter is ignored.

```
a|
-privileged-user-name user_name
a|
No (unless privileged access is enabled)
a|
```

None

a|

Allow passthrough-read

Specifies whether the FPolicy servers can provide passthrough-read services for files that have been archived to secondary storage (offline files) by the FPolicy servers:

- Passthrough-read is a way to read data for offline files without restoring the data to the primary storage.

Passthrough-read reduces response latencies because there is no need to recall files back to primary storage before responding to the read request. Additionally, passthrough-read optimizes storage efficiency by eliminating the need to consume primary storage space with files that are recalled solely to satisfy read requests.

- When enabled, the FPolicy servers provide the data for the file over a separate privileged data channel opened specifically for passthrough-reads.
- If you want to configure passthrough-read, the policy must also be configured to allow privileged access.

a|

-is-passthrough-read-enabled {true\|false}

a|

No

a|

false

= Requirement for FPolicy scope configurations if the FPolicy policy uses the native engine
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.authentication/../media/

[.lead]

If you configure the FPolicy policy to use the native engine, there is a specific requirement for how you define the FPolicy scope configured for the policy.

The FPolicy scope defines the boundaries on which the FPolicy policy applies, for example whether the FPolicy applies to specified volumes or shares. There are a number of parameters that further restrict the scope to which the FPolicy policy applies. One of these parameters, `-is-file-extension-check-on-directories-enabled`, specifies whether to check file extensions on directories. The default value is `false`, which means that file extensions on directories are not checked.

When an FPolicy policy that uses the native engine is enabled on a share or volume and the `-is-file-extension-check-on-directories-enabled` parameter is set to `false` for the scope of the policy, directory access is denied. With this configuration, because the file extensions are not checked for directories, any directory operation is denied if it falls under the scope of the policy.

To ensure that directory access succeeds when using the native engine, you must set the `-is-file-extension-check-on-directories-enabled` parameter to `true` when creating the scope.

With this parameter set to `true`, extension checks happen for directory operations and the decision whether to allow or deny access is taken based on the extensions included or excluded in the FPolicy scope configuration.

= Complete the FPolicy policy worksheet
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.authentication/../media/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.authentication/../media/

[.lead]

Before you configure the FPolicy scope, you must understand what it means to create a scope. You must understand what the scope configuration contains. You also need to understand what the scope rules of precedence are. This information can help you plan the values that you want to set.

== What it means to create an FPolicy scope

Creating the FPolicy scope means defining the boundaries on which the FPolicy policy applies. The storage virtual machine (SVM) is the basic boundary. When you create a scope for an FPolicy policy, you must define the FPolicy policy to which it will apply, and you must designate to which SVM you want to apply the scope.

There are a number of parameters that further restrict the scope within the specified SVM. You can restrict the scope by specifying what to include in the scope or by specifying what to exclude from the scope. After you apply a scope to an enabled policy, policy event checks get applied to the scope defined by this command.

Notifications are generated for file access events where matches are found in the “include” options. Notifications are not generated for file access events where matches are found in the “exclude” options.

The FPolicy scope configuration defines the following configuration information:

- * SVM name
- * Policy name
- * The shares to include or exclude from what gets monitored
- * The export policies to include or exclude from what gets monitored
- * The volumes to include or exclude from what gets monitored
- * The file extensions to include or exclude from what gets monitored
- * Whether to do file extension checks on directory objects

[NOTE]

There are special considerations for the scope for a cluster FPolicy policy. The cluster FPolicy policy is a policy that the cluster administrator creates for the admin SVM. If the cluster administrator also creates the scope for that cluster FPolicy policy, the SVM administrator cannot create a scope for that same policy. However, if the cluster administrator does not create a scope for the cluster FPolicy policy, then any SVM administrator can create the scope for that cluster policy. If the SVM administrator creates a scope for that cluster FPolicy policy, the cluster administrator cannot subsequently create a cluster scope for that same cluster policy. This is because the cluster administrator cannot override the scope for the same cluster policy.

== What the scope rules of precedence are

The following rules of precedence apply to scope configurations:

- When a share is included in the `-shares-to-include` parameter and the parent volume of the share is included in the `-volumes-to-exclude` parameter, `-volumes-to-exclude` has precedence over `-shares-to-include`.
- When an export policy is included in the `-export-policies-to-include` parameter and the parent volume of the export policy is included in the `-volumes-to-exclude` parameter, `-volumes-to-exclude` has precedence over `-export-policies-to-include`.
- An administrator can specify both `-file-extensions-to-include` and `-file-extensions-to-exclude` lists.

The `-file-extensions-to-exclude` parameter is checked before the `-file-extensions-to-include` parameter is checked.

== What the FPolicy scope configuration contains

You can use the following list of available FPolicy scope configuration parameters to help you plan your configuration:

When configuring what shares, export policies, volumes, and file extensions to include or exclude from the scope, the include and exclude parameters can include metacharacters such as "?" and "*". The use of regular expressions is not supported.

Type of information	Option
SVM Specifies the SVM name on which you want to create an FPolicy scope. Each FPolicy configuration is defined within a single SVM. The external engine, policy event, policy scope, and policy that combine together to create an FPolicy policy configuration must all be associated with the same SVM.	-vserver vserver_name
Policy name Specifies the name of the FPolicy policy to which you want to attach the scope. The FPolicy policy must already exist.	-policy-name policy_name
Shares to include Specifies a comma-delimited list of shares to monitor for the FPolicy policy to which the scope is applied.	-shares-to-include share_name, ...
Shares to exclude Specifies a comma-delimited list of shares to exclude from monitoring for the FPolicy policy to which the scope is applied.	-shares-to-exclude share_name, ...
Volumes to include Specifies a comma-delimited list of volumes to monitor for the FPolicy policy to which the scope is applied.	-volumes-to-include volume_name, ...
Volumes to exclude Specifies a comma-delimited list of volumes to exclude from monitoring for the FPolicy policy to which the scope is applied.	-volumes-to-exclude volume_name, ...
Export policies to include Specifies a comma-delimited list of export policies to monitor for the FPolicy policy to which the scope is applied.	-export-policies-to -include export_policy_name, ...
Export policies to exclude Specifies a comma-delimited list of export policies to exclude from monitoring for the FPolicy policy to which the scope is applied.	-export-policies-to -exclude export_policy_name, ...
File extensions to include Specifies a comma-delimited list of file extensions to monitor for the FPolicy policy to which the scope is applied.	-file-extensions-to -include file_extensions, ...

File extension to exclude	-file-extensions-to-exclude file_extensions, ...
Is file extension check on directory enabled ?	-is-file-extension-check-on-directories-enabled {true false }

= Complete the FPolicy scope worksheet

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.authentication/..media/

You can use this worksheet to record the values that you need during the FPolicy scope configuration process. If a parameter value is required, you need to determine what value to use for those parameters before you configure the FPolicy scope.

You should record whether you want to include each parameter setting in the FPolicy scope configuration and then record the value for the parameters that you want to include.

Type of information	Required	Include	Your values

Shares to exclude	No		
Volumes to include	No		
Volumes to exclude	No		
Export policies to include	No		
Export policies to exclude	No		
File extensions to include	No		

File extension to exclude	No		
Is file extension check on directory enabled?	No		

= Create the FPolicy configuration

= Create the FPolicy external engine

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./authentication../media/

You must create an external engine to start creating an FPolicy configuration. The external engine defines how FPolicy makes and manages connections to external FPolicy servers. If your configuration uses the internal ONTAP engine (the native external engine) for simple file blocking, you do not need to configure a separate FPolicy external engine and do not need to perform this step.

What you'll need

The [external engine](#) worksheet should be completed.

About this task

If the external engine is used in a MetroCluster configuration, you should specify the IP addresses of the FPolicy servers at the source site as primary servers. The IP addresses of the FPolicy servers at the destination site should be specified as secondary servers.

Steps

1. Create the FPolicy external engine by using the `vserver fpolicy policy external-engine create` command.

The following command creates an external engine on storage virtual machine (SVM) `vs1.example.com`. No authentication is required for external communications with the FPolicy server.

```
vserver fpolicy policy external-engine create -vserver-name vs1.example.com
-engine-name engine1 -primary-servers 10.1.1.2,10.1.1.3 -port 6789 -ssl
-option no-auth
```

2. Verify the FPolicy external engine configuration by using the `vserver fpolicy policy external-engine show` command.

The following command display information about all external engines configured on SVM `vs1.example.com`:

```
vserver fpolicy policy external-engine show -vserver vs1.example.com
```

		Primary	Secondary	
External Vserver	Engine	Servers	Servers	Port
Engine Type				
vs1.example.com	engine1	10.1.1.2, 10.1.1.3	-	6789
synchronous				

The following command displays detailed information about the external engine named “engine1” on SVM vs1.example.com:

```
vserver fpolicy policy external-engine show -vserver vs1.example.com
-engine-name engine1
```

```
Vserver: vs1.example.com
Engine: engine1
Primary FPolicy Servers: 10.1.1.2, 10.1.1.3
Port Number of FPolicy Service: 6789
Secondary FPolicy Servers: -
External Engine Type: synchronous
SSL Option for External Communication: no-auth
FQDN or Custom Common Name: -
Serial Number of Certificate: -
Certificate Authority: -
```

= Create the FPolicy event

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./authentication./media/

As part of creating an FPolicy policy configuration, you need to create an FPolicy event. You associate the event with the FPolicy policy when it is created. An event defines which protocol to monitor and which file access events to monitor and filter.

Before you begin

You should complete the FPolicy event [worksheet](#).

-- Create the FPolicy event

1. Create the FPolicy event by using the `vserver fpolicy policy event create` command.

```
vserver fpolicy policy event create -vserver vs1.example.com -event-name
event1 -protocol cifs -file-operations open,close,read,write
```

- Verify the FPolicy event configuration by using the vserver fpolicy policy event show command.

```
vserver fpolicy policy event show -vserver vs1.example.com
```

Event	File	Is
Volume	Name	Protocols Operations Filters
Vserver		
Operation		
-----	-----	-----
-----	-----	-----
vs1.example.com	event1	cifs open, close, - read, write
		false

== Create the FPolicy access denied events

Beginning with ONTAP 9.13.1, users can receive notifications for failed file operations due to lack of permissions. These notifications are valuable for security, ransomware protection, and governance.

- Create the FPolicy event by using the vserver fpolicy policy event create command.

```
vserver fpolicy policy event create -vserver vs1.example.com -event-name event1 -protocol cifs -monitor-fileop-failure true -file-operations open
```

= Create the FPolicy policy

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./authentication../media/

When you create the FPolicy policy, you associate an external engine and one or more events to the policy. The policy also specifies whether mandatory screening is required, whether the FPolicy servers have privileged access to data on the storage virtual machine (SVM), and whether passthrough-read for offline files is enabled.

What you'll need

- The FPolicy policy worksheet should be completed.
- If you plan on configuring the policy to use FPolicy servers, the external engine must exist.
- At least one FPolicy event that you plan on associating with the FPolicy policy must exist.
- If you want to configure privileged data access, a SMB server must exist on the SVM.

Steps

- Create the FPolicy policy:

```
vserver fpolicy policy create -vserver-name vserver_name -policy-name policy_name -engine engine_name -events event_name,... [-is-mandatory {true|false}] [-allow-privileged-access {yes|no}] [-privileged-user-name domain\user_name] [-is-passthrough-read-enabled {true|false}]
```

- You can add one or more events to the FPolicy policy.
- By default, mandatory screening is enabled.
- If you want to allow privileged access by setting the `-allow-privileged-access` parameter to yes, you must also configure a privileged user name for privileged access.
- If you want to configure passthrough-read by setting the `-is-passthrough-read-enabled` parameter to true, you must also configure privileged data access.

The following command creates a policy named “policy1” that has the event named “event1” and the external engine named “engine1” associated with it. This policy uses default values in the policy configuration:

```
vserver fpolicy policy create -vserver vs1.example.com -policy-name
policy1 -events event1 -engine engine1
```

The following command creates a policy named “policy2” that has the event named “event2” and the external engine named “engine2” associated with it. This policy is configured to use privileged access using the specified user name. Passthrough-read is enabled:

```
vserver fpolicy policy create -vserver vs1.example.com -policy-name
policy2 -events event2 -engine engine2 -allow-privileged-access yes
-privileged-user-name example\archive_acct -is-passthrough-read-enabled
true
```

The following command creates a policy named “native1” that has the event named “event3” associated with it. This policy uses the native engine and uses default values in the policy configuration:

```
vserver fpolicy policy create -vserver vs1.example.com -policy-name
native1 -events event3 -engine native
```

2. Verify the FPolicy policy configuration by using the `vserver fpolicy policy show` command.

The following command displays information about the three configured FPolicy policies, including the following information:

- The SVM associated with the policy
- The external engine associated with the policy
- The events associated with the policy
- Whether mandatory screening is required
- Whether privileged access is required

```
vserver fpolicy policy show
```

Vserver	Policy	Events	Engine	Is Mandatory	
Privileged	Name				Access
vs1.example.com	policy1	event1	engine1	true	no
vs1.example.com	policy2	event2	engine2	true	yes
vs1.example.com	native1	event3	native	true	no

= Create the FPolicy scope

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./authentication./media/

After creating the FPolicy policy, you need to create an FPolicy scope. When creating the scope, you associate the scope with an FPolicy policy. A scope defines the boundaries on which the FPolicy policy applies. Scopes can include or exclude files based on shares, export policies, volumes, and file extensions.

What you'll need

The FPolicy scope worksheet must be completed. The FPolicy policy must exist with an associated external engine (if the policy is configured to use external FPolicy servers) and must have at least one associated FPolicy event.

Steps

1. Create the FPolicy scope by using the vserver fpolicy policy scope create command.

```
vserver fpolicy policy scope create -vserver-name vs1.example.com -policy
-name policy1 -volumes-to-include datavol1,datavol2
```

2. Verify the FPolicy scope configuration by using the vserver fpolicy policy scope show command.

```
vserver fpolicy policy scope show -vserver vs1.example.com -instance
```

```
Vserver: vs1.example.com
Policy: policy1
Shares to Include: -
Shares to Exclude: -
Volumes to Include: datavol1, datavol2
Volumes to Exclude: -
Export Policies to Include: -
Export Policies to Exclude: -
File Extensions to Include: -
File Extensions to Exclude: -
```

```
= Enable the FPolicy policy
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./authentication./media/
```

After you are through configuring an FPolicy policy configuration, you enable the FPolicy policy. Enabling the policy sets its priority and starts file access monitoring for the policy.

What you'll need

The FPolicy policy must exist with an associated external engine (if the policy is configured to use external FPolicy servers) and must have at least one associated FPolicy event. The FPolicy policy scope must exist and must be assigned to the FPolicy policy.

About this task

The priority is used when multiple policies are enabled on the storage virtual machine (SVM) and more than one policy has subscribed to the same file access event. Policies that use the native engine configuration have a higher priority than policies for any other engine, regardless of the sequence number assigned to them when enabling the policy.

A policy cannot be enabled on the admin SVM.

Steps

1. Enable the FPolicy policy by using the `vserver fpolicy enable` command.

```
vserver fpolicy enable -vserver-name vs1.example.com -policy-name policy1  
-sequence-number 1
```

2. Verify that the FPolicy policy is enabled by using the `vserver fpolicy show` command.

```
vserver fpolicy show -vserver vs1.example.com
```

Vserver	Policy Name	Sequence Number	Status	Engine
vs1.example.com	policy1	1	on	engine1

= Modify FPolicy configurations

= Commands for modifying FPolicy configurations

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./authentication../media/

You can modify FPolicy configurations by modifying the elements that make up the configuration. You can modify external engines, FPolicy events, FPolicy scopes, and FPolicy policies. You can also enable or disable FPolicy policies. When you disable the FPolicy policy, file monitoring is discontinued for that policy.

It is recommended to disable the FPolicy policy before modifying the configuration.

If you want to modify...	Use this command...
External engines	<code>vserver fpolicy policy external-engine modify</code>
Events	<code>vserver fpolicy policy event modify</code>
Scopes	<code>vserver fpolicy policy scope modify</code>
Policies	<code>vserver fpolicy policy modify</code>

See the man pages for the commands for more information.

= Enable or disable FPolicy policies

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./authentication../media/

You can enable FPolicy policies after the configuration is complete. Enabling the policy sets its priority and starts file access monitoring for the policy. You can disable FPolicy policies if you want to stop file access monitoring for the policy.

What you'll need

Before enabling FPolicy policies, the FPolicy configuration must be completed.

About this task

- The priority is used when multiple policies are enabled on the storage virtual machine (SVM) and more than one policy has subscribed to the same file access event.
- Policies that use the native engine configuration have a higher priority than policies for any other engine, regardless of the sequence number assigned to them when enabling the policy.
- If you want to change the priority of an FPolicy policy, you must disable the policy and then reenable it using the new sequence number.

Step

1. Perform the appropriate action:

If you want to...	Enter the following command...
Enable an FPolicy policy	vserver fpolicy enable -vserver-name vserver_name -policy-name policy_name -sequence -number integer
Disable an FPolicy policy	vserver fpolicy disable -vserver-name vserver_name -policy-name policy_name

= Display information about FPolicy configurations

= How the show commands work

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source//authentication//media/

It is helpful when displaying information about the FPolicy configuration to understand how the show commands work.

A show command without additional parameters displays information in a summary form. Additionally, every show command has the same two mutually exclusive optional parameters, -instance and -fields.

When you use the -instance parameter with a show command, the command output displays detailed information in a list format. In some cases, the detailed output can be lengthy and include more information than you need. You can use the -fields fieldname [, fieldname...] parameter to customize the output so that it displays information only for the fields you specify. You can identify which fields that you can specify by entering ? after the -fields parameter.

The output of a show command with the -fields parameter might display other relevant and necessary fields

related to the requested fields.

Every `show` command has one or more optional parameters that filter that output and enable you to narrow the scope of information displayed in command output. You can identify which optional parameters are available for a command by entering `?` after the `show` command.

The `show` command supports UNIX-style patterns and wildcards to enable you to match multiple values in command-parameters arguments. For example, you can use the wildcard operator (*), the NOT operator (!), the OR operator (|), the range operator (integer...integer), the less-than operator (<), the greater-than operator (>), the less-than or equal to operator (<=), and the greater-than or equal to operator (>=) when specifying values.

For more information about using UNIX-style patterns and wildcards, see the [Using the ONTAP command-line interface](#).

= Commands for displaying information about FPolicy configurations

You use the `fpolicy show` commands to display information about the FPolicy configuration, including information about FPolicy external engines, events, scopes, and policies.

If you want to display information about FPolicy...	Use this command...
External engines	<code>vserver fpolicy policy external-engine show</code>
Events	<code>vserver fpolicy policy event show</code>
Scopes	<code>vserver fpolicy policy scope show</code>
Policies	<code>vserver fpolicy policy show</code>

See the man pages for the commands for more information.

= Display information about FPolicy policy status

You can display information about the status for FPolicy policies to determine whether a policy is enabled, what external engine it is configured to use, what the sequence number is for the policy, and to which storage virtual machine (SVM) the FPolicy policy is associated.

About this task

If you do not specify any parameters, the command displays the following information:

- SVM name
- Policy name
- Policy sequence number
- Policy status

In addition to displaying information about policy status for FPolicy policies configured on the cluster or a

specific SVM, you can use command parameters to filter the command's output by other criteria.

You can specify the `-instance` parameter to display detailed information about listed policies. Alternatively, you can use the `-fields` parameter to display only the indicated fields in the command output, or `-fields ?` to determine what fields you can use.

Step

1. Display filtered information about FPolicy policy status by using the appropriate command:

If you want to display status information about policies...	Enter the command...
On the cluster	<code>vserver fpolicy show</code>
That have the specified status	<code>vserver fpolicy show -status {on off}</code>
On a specified SVM	<code>vserver fpolicy show -vserver vserver_name</code>
With the specified policy name	<code>vserver fpolicy show -policy-name policy_name</code>
That use the specified external engine	<code>vserver fpolicy show -engine engine_name</code>

Example

The following example displays the information about FPolicy policies on the cluster:

```
cluster1::> vserver fpolicy show
          Sequence
Vserver      Policy Name      Number  Status   Engine
-----      -----
FPolicy      cserver_policy  -        off     eng1
vs1.example.com  v1p1        -        off     eng2
vs1.example.com  v1p2        -        off     native
vs1.example.com  v1p3        -        off     native
vs1.example.com  cserver_policy  -        off     eng1
vs2.example.com  v1p1        3        on      native
vs2.example.com  v1p2        1        on      eng3
vs2.example.com  cserver_policy  2        on      eng1
```

= Display information about enabled FPolicy policies

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

You can display information about enabled FPolicy policies to determine what FPolicy external engine it is configured to use, what the priority is for the policy, and to which

storage virtual machine (SVM) the FPolicy policy is associated.

About this task

If you do not specify any parameters, the command displays the following information:

- SVM name
- Policy name
- Policy priority

You can use command parameters to filter the command's output by specified criteria.

Step

1. Display information about enabled FPolicy policies by using the appropriate command:

If you want to display information about enabled policies...	Enter the command...
On the cluster	vserver fpolicy show-enabled
On a specified SVM	vserver fpolicy show-enabled -vserver vserver_name
With the specified policy name	vserver fpolicy show-enabled -policy-name policy_name
With the specified sequence number	vserver fpolicy show-enabled -priority integer

Example

The following example displays the information about enabled FPolicy policies on the cluster:

```
cluster1::> vserver fpolicy show-enabled
Vserver          Policy Name          Priority
-----
vs1.example.com    pol_native        native
vs1.example.com    pol_native2       native
vs1.example.com    pol1             2
vs1.example.com    pol2             4
```

= Manage FPolicy server connections

= Connect to external FPolicy servers

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

To enable file processing, you might need to manually connect to an external FPolicy server if the connection has previously been terminated. A connection is terminated after the server timeout is reached or due to some error. Alternatively, the administrator might manually terminate a connection.

About this task

If a fatal error occurs, the connection to the FPolicy server can be terminated. After resolving the issue that caused the fatal error, you must manually reconnect to the FPolicy server.

Steps

1. Connect to the external FPolicy server by using the `vserver fpolicy engine-connect` command.

For more information about the command, see the man pages.

2. Verify that the external FPolicy server is connected by using the `vserver fpolicy show-engine` command.

For more information about the command, see the man pages.

= Disconnect from external FPolicy servers

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

You might need to manually disconnect from an external FPolicy server. This might be desirable if the FPolicy server has issues with notification request processing or if you need to perform maintenance on the FPolicy server.

Steps

1. Disconnect from the external FPolicy server by using the `vserver fpolicy engine-disconnect` command.

For more information about the command, see the man pages.

2. Verify that the external FPolicy server is disconnected by using the `vserver fpolicy show-engine` command.

For more information about the command, see the man pages.

= Display information about connections to external FPolicy servers

You can display status information about connections to external FPolicy servers (FPolicy servers) for the cluster or for a specified storage virtual machine (SVM). This information can help you determine which FPolicy servers are connected.

About this task

If you do not specify any parameters, the command displays the following information:

- SVM name

- Node name
- FPolicy policy name
- FPolicy server IP address
- FPolicy server status
- FPolicy server type

In addition to displaying information about FPolicy connections on the cluster or a specific SVM, you can use command parameters to filter the command's output by other criteria.

You can specify the `-instance` parameter to display detailed information about listed policies. Alternatively, you can use the `-fields` parameter to display only the indicated fields in the command output. You can enter `?` after the `-fields` parameter to find out which fields you can use.

Step

1. Display filtered information about connection status between the node and the FPolicy server by using the appropriate command:

If you want to display connection status information about FPolicy servers...	Enter...
That you specify	<code>vserver fpolicy show-engine -server IP_address</code>
For a specified SVM	<code>vserver fpolicy show-engine -vserver vserver_name</code>
That are attached with a specified policy	<code>vserver fpolicy show-engine -policy-name policy_name</code>
With the server status that you specify	<p><code>vserver fpolicy show-engine -server-status status</code></p> <p>The server status can be one of the following:</p> <ul style="list-style-type: none"> • connected • disconnected • connecting • disconnecting
With the specified type	<p><code>vserver fpolicy show-engine -server-type type</code></p> <p>The FPolicy server type can be one of the following:</p> <ul style="list-style-type: none"> • primary • secondary

That were disconnected with the specified reason

```
vserver fpolicy show-engine -disconnect-reason  
text
```

Disconnect can be due to multiple reasons. The following are common reasons for disconnect:

- Disconnect command received from CLI.
- Error encountered while parsing notification response from FPolicy server.
- FPolicy Handshake failed.
- SSL handshake failed.
- TCP Connection to FPolicy server failed.
- The screen response message received from the FPolicy server is not valid.

Example

This example displays information about external engine connections to FPolicy servers on SVM vs1.example.com:

```
cluster1::> vserver fpolicy show-engine -vserver vs1.example.com  
FPolicy  
Server-  
Server-  
Vserver Policy Node Server status type  
----- -----  
-----  
vs1.example.com policy1 node1 10.1.1.2 connected  
primary  
vs1.example.com policy1 node1 10.1.1.3 disconnected  
primary  
vs1.example.com policy1 node2 10.1.1.2 connected  
primary  
vs1.example.com policy1 node2 10.1.1.3 disconnected  
primary
```

This example displays information only about connected FPolicy servers:

```
cluster1::> vserver fpolicy show-engine -fields server -server-status  
connected  
node vserver policy-name server  
-----  
node1 vs1.example.com policy1 10.1.1.2  
node2 vs1.example.com policy1 10.1.1.2
```

= Display information about the FPolicy passthrough-read connection status

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

You can display information about FPolicy passthrough-read connection status to external FPolicy servers (FPolicy servers) for the cluster or for a specified storage virtual machine (SVM). This information can help you determine which FPolicy servers have passthrough-read data connections and for which FPolicy servers the passthrough-read connection is disconnected.

About this task

If you do not specify any parameter, the command displays the following information:

- SVM name
- FPolicy policy name
- Node name
- FPolicy server IP address
- FPolicy passthrough-read connection status

In addition to displaying information about FPolicy connections on the cluster or a specific SVM, you can use command parameters to filter the command's output by other criteria.

You can specify the `-instance` parameter to display detailed information about listed policies. Alternatively, you can use the `-fields` parameter to display only the indicated fields in the command output. You can enter `?` after the `-fields` parameter to find out which fields you can use.

Step

1. Display filtered information about connection status between the node and the FPolicy server by using the appropriate command:

If you want to display connection status information about...	Enter the command...
FPolicy passthrough-read connection status for the cluster	<code>vserver fpolicy show-passthrough-read-connection</code>
FPolicy passthrough-read connection status for a specified SVM	<code>vserver fpolicy show-passthrough-read-connection -vserver vserver_name</code>
FPolicy passthrough-read connection status for a specified policy	<code>vserver fpolicy show-passthrough-read-connection -policy-name policy_name</code>
Detailed FPolicy passthrough-read connection status for a specified policy	<code>vserver fpolicy show-passthrough-read-connection -policy-name policy_name -instance</code>

FPolicy passthrough-read connection status for the status that you specify

vserver fpolicy show-passthrough-read-connection -policy-name policy_name -server -status status The server status can be one of the following:

- connected
- disconnected

Example

The following command displays information about passthrough-read connections from all FPolicy servers on the cluster:

```
cluster1::> vserver fpolicy show-passthrough-read-connection
              FPolicy          Server
Vserver      Policy Name   Node       Server      Status
-----  -----  -----  -----
-----  -----
vs2.example.com  pol_cifs_2    FPolicy-01    2.2.2.2
disconnected
vs1.example.com  pol_cifs_1    FPolicy-01    1.1.1.1           connected
```

The following command displays detailed information about passthrough-read connections from FPolicy servers configured in the “pol_cifs_1” policy:

```
cluster1::> vserver fpolicy show-passthrough-read-connection -policy
              -name pol_cifs_1 -instance
                               Node: FPolicy-01
                               Vserver: vs1.example.com
                               Policy: pol_cifs_1
                               Server: 1.1.1.1
Session ID of the Control Channel: 8cef052e-2502-11e3-
88d4-123478563412
                               Server Status: connected
Time Passthrough Read Channel was Connected: 9/24/2013 10:17:45
Time Passthrough Read Channel was Disconnected: -
Reason for Passthrough Read Channel Disconnection: none
```

= Use security tracing to verify or troubleshoot file and directory access

= How security traces work

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

You can add permission tracing filters to instruct ONTAP to log information about why the SMB and NFS servers on a storage virtual machine (SVM) allows or denies a client or user's request to perform an operation. This can be useful when you want to verify that your file access security scheme is appropriate or when you want to troubleshoot file access issues.

Security traces allow you to configure a filter that detects client operations over SMB and NFS on the SVM, and trace all access checks matching that filter. You can then view the trace results, which provides a convenient summary of the reason that access was allowed or denied.

When you want to verify the security settings for SMB or NFS access on files and folders on your SVM or if you are faced with an access problem, you can quickly add a filter to turn on permission tracing.

The following list outlines important facts about how security traces works:

- ONTAP applies security traces at the SVM level.
- Each incoming request is screened to see if it matches filtering criteria of any enabled security traces.
- Traces are performed for both file and folder access requests.
- Traces can filter based on the following criteria:
 - Client IP
 - SMB or NFS path
 - Windows name
 - UNIX name
- Requests are screened for *Allowed* and *Denied* access response results.
- Each request matching filtering criteria of enabled traces is recorded in the trace results log.
- The storage administrator can configure a timeout on a filter to automatically disable it.
- If a request matches multiple filters, the results from the filter with the highest index number is recorded.
- The storage administrator can print results from the trace results log to determine why an access request was allowed or denied.

= Types of access checks security traces monitor

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

Access checks for a file or folder are done based on multiple criteria. Security traces monitor operations on all these criteria.

The types of access checks that security traces monitor include the following:

- Volume and qtree security style
- Effective security of the file system containing the files and folders on which operations are requested
- User mapping
- Share-level permissions
- Export-level permissions

- File-level permissions
- Storage-Level Access Guard security

= Considerations when creating security traces

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

You should keep several considerations in mind when you create security traces on storage virtual machines (SVMs). For example, you need to know on which protocols you can create a trace, which security-styles are supported, and what the maximum number of active traces is.

- You can only create security traces on SVMs.
- Each security trace filter entry is SVM specific.

You must specify the SVM on which you want to run the trace.

- You can add permission tracing filters for SMB and NFS requests.
- You must set up the SMB or NFS server on the SVM on which you want to create trace filters.
- You can create security traces for files and folders residing on NTFS, UNIX, and mixed security-style volumes and qtrees.
- You can add a maximum of 10 permission tracing filters per SVM.
- You must specify a filter index number when creating or modifying a filter.

Filters are considered in order of the index number. The criteria in a filter with a higher index number is considered before the criteria with a lower index number. If the request being traced matches criteria in multiple enabled filters, only the filter with the highest index number is triggered.

- After you have created and enabled a security trace filter, you must perform some file or folder requests on a client system to generate activity that the trace filter can capture and log in the trace results log.
- You should add permission tracing filters for file access verification or troubleshooting purposes only.

Adding permission tracing filters has a minor effect on controller performance.

When you are done with verification or troubleshooting activity, you should disable or remove all permission tracing filters. Furthermore, the filtering criteria you select should be as specific as possible so that ONTAP does not send a large number of trace results to the log.

= Perform security traces

= Perform security traces overview

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

Performing a security trace involves creating a security trace filter, verifying the filter criteria, generating access requests on an SMB or NFS client that match filter criteria, and viewing the results.

After you are finished using a security filter to capture trace information, you can modify the filter and reuse it, or disable it if you no longer need it. After viewing and analyzing the filter trace results, you can then delete them if they are no longer needed.

= Create security trace filters
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

You can create security trace filters that detect SMB and NFS client operations on storage virtual machines (SVMs) and trace all access checks matching the filter. You can use the results from security traces to validate your configuration or to troubleshoot access issues.

About this task

There are two required parameters for the vserver security trace filter create command:

Required parameters	Description
-vserver vserver_name	<p><i>SVM name</i></p> <p>The name of the SVM that contains the files or folders on which you want to apply the security trace filter.</p>
-index index_number	<p><i>Filter index number</i></p> <p>The index number you want to apply to the filter. You are limited to a maximum of 10 trace filters per SVM. The allowed values for this parameter are 1 through 10.</p>

A number of optional filter parameters enable you to customize the security trace filter so that you can narrow down the results produced by the security trace:

Filter parameter	Description
-client-ip IP_Address	This filter specifies the IP address from which the user is accessing the SVM.
-path path	<p>This filter specifies the path on which to apply the permission trace filter. The value for <code>-path</code> can use either of the following formats:</p> <ul style="list-style-type: none">• The complete path, starting from the root of the share or export• A partial path, relative to the root of the share <p>You must use NFS style directory UNIX-style directory separators in the path value.</p>

```
-windows-name  
win_user_name or -unix  
-name ``unix_user_name
```

You can specify either the Windows user name or UNIX user name whose access requests you want to trace. The user name variable is case insensitive. You cannot specify both a Windows user name and a UNIX user name in the same filter.

Even though you can trace SMB and NFS access events, the mapped UNIX user and the mapped UNIX users' groups might be used when performing access checks on mixed or UNIX security-style data.

```
a|
-trace-allow {yes\|no}
a|
Tracing for deny events is always enabled for a security trace filter. You can optionally trace allow events.
To trace allow events, you set this parameter to yes.
a|
-enabled {enabled\|disabled}
a|
You can enable or disable the security trace filter. By default, the security trace filter is enabled.
a|
-time-enabled integer
a|
You can specify a timeout for the filter, after which it is disabled.
```

.Steps

. Create a security trace filter:

```
+  
vserver security trace filter create -vserver vserver_name -index  
index_numberfilter_parameters
```

+
filter_parameters is a list of optional filter parameters.

+

For more information, see the man pages for the command.

. Verify the security trace filter entry:

+

```
vserver security trace filter show -vserver vserver_name -index index_number
```

.Examples

The following command creates a security trace filter for any user accessing a file with a share path \\server\share1\dir1\dir2\file.txt from the IP address 10.10.10.7. The filter uses a complete path for the -path option. The client's IP address used to access data is 10.10.10.7. The filter times out after 30 minutes:

```
----  
cluster1::> vserver security trace filter create -vserver vs1 -index 1 -path /dir1/dir2/file.txt -time-enabled  
30 -client-ip 10.10.10.7
```

```
cluster1::> vserver security trace filter show -index 1  
Vserver Index Client-IP Path Trace-Allow Windows-Name  
-----  
vs1 1 10.10.10.7 /dir1/dir2/file.txt no -  
----
```

The following command creates a security trace filter using a relative path for the -path option. The filter traces access for a Windows user named "joe". Joe is accessing a file with a share path \\server\share1\dir1\dir2\file.txt. The filter traces allow and deny events:

```
----  
cluster1::> vserver security trace filter create -vserver vs1 -index 2 -path /dir1/dir2/file.txt -trace-allow yes  
-windows-name mydomain\joe
```

```
cluster1::> vserver security trace filter show -vserver vs1 -index 2
```

```
Vserver: vs1
```

```
Filter Index: 2
```

```
Client IP Address to Match: -
```

```
Path: /dir1/dir2/file.txt
```

```
Windows User Name: mydomain\joe
```

```
UNIX User Name: -
```

```
Trace Allow Events: yes
```

```
Filter Enabled: enabled
```

```
Minutes Filter is Enabled: 60
```

```
----
```

h| If the filter is configured... h| Then...

- a| With a UNIX user name
- a| The security trace result displays the UNIX user name.
- a| With a Windows user name
- a| The security trace result displays the Windows user name.
- a| Without a user name
- a| The security trace result displays the Windows user name.

You can customize the output by using optional parameters. Some of the optional parameters that you can use to narrow the results returned in the command output include the following:

[cols="35,65"]

h| Optional parameter h| Description

- a| -fields field_name, ...
 - a| Displays output on the fields you choose. You can use this parameter either alone or in combination with other optional parameters.
- a| -instance
 - a| Displays detailed information about security trace events. Use this parameter with other optional parameters to display detailed information about specific filter results.
- a| -node node_name
 - a| Displays information only about events on the specified node.
- a| -vserver vserver_name
 - a| Displays information only about events on the specified SVM.
- a| -index integer
 - a| Displays information about the events that occurred as a result of the filter corresponding to the specified index number.
- a| -client-ip IP_address
 - a| Displays information about the events that occurred as a result of file access from the specified client IP address.
- a| -path path
 - a| Displays information about the events that occurred as a result of file access to the specified path.

a|
-user-name user_name
a|
Displays information about the events that occurred as a result of file access by the specified Windows or UNIX user.
a|
-security-style security_style
a|
Displays information about the events that occurred on file systems with the specified security style.

See the man page for information about other optional parameters that you can use with the command.

.Step

. Display security trace filter results by using the vserver security trace trace-result show command.

+

```
vserver security trace trace-result show -user-name domain\user
```

+

Vserver: vs1

Node Index Filter Details Reason

node1 3 User:domain\user Access denied by explicit ACE

Security Style:mixed

Path:/dir1/dir2/

node1 5 User:domain\user Access denied by explicit ACE

Security Style:unix

Path:/dir1/

= Modify security trace filters

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

[.lead]

If you want to change the optional filter parameters used to determine which access events are traced, you can modify existing security trace filters.

.About this task

You must identify which security trace filter you want to modify by specifying the storage virtual machine (SVM) name on which the filter is applied and the index number of the filter. You can modify all the optional filter parameters.

.Steps

. Modify a security trace filter:

+

```
vserver security trace filter modify -vserver vserver_name -index  
index_numberfilter_parameters
```

+

vserver_name is the name of the SVM on which you want to apply a security trace filter.

index_number is the index number that you want to apply to the filter. The allowed values for this parameter are 1 through 10.

**** filter_parameters** is a list of optional filter parameters.

. Verify the security trace filter entry:

+

Each storage virtual machine (SVM) can store a maximum of 128 trace records. If the maximum is reached on the SVM, the oldest trace records are automatically deleted as new ones are added. If you do not want to manually delete trace records on this SVM, you can let ONTAP automatically delete the oldest trace results after the maximum is reached to make room for new results.

Steps

1. Identify the sequence number of the record you want to delete:

```
vserver security trace trace-result show -vserver vserver_name -instance
```

2. Delete the security trace record:

```
vserver security trace trace-result delete -node node_name -vserver  
vserver_name -seqnum integer
```

```
vserver security trace trace-result delete -vserver vs1 -node node1 -seqnum  
999
```

- `-node node_name` is the name of the cluster node on which the permission tracing event that you want to delete occurred.

This is a required parameter.

- `-vserver vserver_name` is the name of the SVM on which the permission tracing event that you want to delete occurred.

This is a required parameter.

- `-seqnum integer` is the sequence number of the log event that you want to delete.

This is a required parameter.

= Delete all security trace records

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

If you do not want to keep any of the existing security trace records, you can delete all of the records on a node with a single command.

Step

1. Delete all security trace records:

```
vserver security trace trace-result delete -node node_name -vserver  
vserver_name *
```

- `-node node_name` is the name of the cluster node on which the permission tracing event that you want to delete occurred.

- `-vserver vserver_name` is the name of the storage virtual machine (SVM) on which the permission tracing event that you want to delete occurred.

= Interpret security trace results

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

Security trace results provide the reason that a request was allowed or denied. Output displays the result as a combination of the reason for allowing or denying access and the location within the access checking pathway where access is either allowed or denied. You can use the results to isolate and identify why actions are or are not allowed.

== Finding information about the lists of result types and filter details

You can find the lists of result types and filter details that can be included in the security trace results in the man pages for the vserver security trace trace-result show command.

Example of output from the Reason field in an Allow result type

The following is an example of the output from the Reason field that appears in the trace results log in an Allow result type:

Access is allowed because SMB implicit permission grants requested access while opening existing file or directory.

Access is allowed because NFS implicit permission grants requested access while opening existing file or directory.

Example of output from the Reason field in an Allow result type

The following is an example of the output from the Reason field that appears in the trace results log in a Deny result type:

Access is denied. The requested permissions are not granted by the ACE while checking for child-delete access on the parent.

Example of output from the Filter details field

The following is an example of the output from the Filter details field in the trace results log, which list the effective security style of the file system containing files and folders that match the filter criteria:

Security Style: MIXED and ACL

= Where to find additional information

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

After you have successfully tested SMB client access, you can perform advanced SMB configuration or add SAN access. After you have successfully tested NFS client access, you can perform advanced NFS configuration or add SAN access. When protocol access is complete, you should protect the root volume of SVM.

== SMB configuration

You can further configure SMB access using the following:

- [SMB management](#)

Describes how to configure and manage file access using the SMB protocol.

- [NetApp Technical Report 4191: Best Practices Guide for Clustered Data ONTAP 8.2 Windows File Services](#)

Provides a brief overview of SMB implementation and other Windows File Services features with recommendations and basic troubleshooting information for ONTAP.

- [NetApp Technical Report 3740: SMB 2 Next-Generation CIFS Protocol in Data ONTAP](#)

Describes SMB 2 features, configuration details, and its implementation in ONTAP.

== NFS configuration

You can further configure NFS access using the following:

- [NFS management](#)

Describes how to configure and manage file access using the NFS protocol.

- [NetApp Technical Report 4067: NFS Best Practice and Implementation Guide](#)

Serves as an NFSv3 and NFSv4 operational guide and provides an overview of ONTAP operating system with a focus on NFSv4.

- [NetApp Technical Report 4668: Name Services Best Practices Guide](#)

Provides a comprehensive list of best practices, limits, recommendations, and considerations when configuring LDAP, NIS, DNS, and local user and group files for authentication purposes.

- [NetApp Technical Report 4616: NFS Kerberos in ONTAP with Microsoft Active Directory](#)

- [NetApp Technical Report 4835: How to Configure LDAP in ONTAP](#)

- [NetApp Technical Report 3580: NFSv4 Enhancements and Best Practices Guide Data ONTAP Implementation](#)

Describes the best practices that should be followed while implementing NFSv4 components on AIX, Linux, or Solaris clients attached to systems running ONTAP.

== Root volume protection

After configuring protocols on the SVM, you should ensure that its root volume is protected:

- [Data protection](#)

Describes how to create a load-sharing mirror to protect the SVM root volume, which is a NetApp best practice for NAS-enabled SVMs. Also describes how to quickly recover from volume failures or losses by promoting the SVM root volume from a load-sharing mirror.

= Manage encryption with System Manager

= Encrypt stored data using software-based encryption

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit./media/

Use volume encryption to ensure that volume data cannot be read if the underlying device is repurposed, returned, misplaced, or stolen. Volume encryption does not require special disks; it works with all HDDs and SSDs.

Volume encryption requires a key manager. You can configure the Onboard Key Manager using System Manager. You can also use an external key manager, but you need to first set it up using the ONTAP CLI.

After the key manager is configured, new volumes are encrypted by default.

Steps

1. Click **Cluster > Settings**.
2. Under **Encryption**, click  to configure the Onboard Key Manager for the first time.
3. To encrypt existing volumes, click **Storage > Volumes**.
4. On the desired volume, click  and then click **Edit**.
5. Select **Enable encryption**.

= Encrypt stored data using self-encrypting drives

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit./media/

Use disk encryption to ensure that all data in a local tier cannot be read if the underlying device is repurposed, returned, misplaced, or stolen. Disk encryption requires special self-encrypting HDDs or SSDs.

Disk encryption requires a key manager. You can configure the onboard key manager using System Manager. You can also use an external key manager, but you need to first set it up using the ONTAP CLI.

If ONTAP detects self-encrypting disks, it prompts you to configure the onboard key manager when you create the local tier.

Steps

1. Under **Encryption**, click  to configure the onboard key manager.
2. If you see a message that disks need to be rekeyed, click , and then click **Rekey Disks**.

= Manage encryption with the CLI

= NetApp Encryption overview with the CLI

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit./media/

NetApp offers both software- and hardware-based encryption technologies for ensuring that data at rest cannot be read if the storage medium is repurposed, returned, misplaced, or stolen.

- Software-based encryption using NetApp Volume Encryption (NVE) supports data encryption one volume at a time
- Hardware-based encryption using NetApp Storage Encryption (NSE) supports full-disk encryption (FDE) of data as it is written.

You can work with encryption if the following apply:

- You want to use best practices, not explore every available option.
- You want to use the ONTAP command-line interface (CLI), not System Manager or an automated scripting tool.

= Configure NetApp Volume Encryption

= Configure NetApp Volume Encryption overview

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit./media/

NetApp Volume Encryption (NVE) is a software-based technology for encrypting data at rest one volume at a time. An encryption key accessible only to the storage system ensures that volume data cannot be read if the underlying device is repurposed, returned, misplaced, or stolen.

== Understanding NVE

Both data, including Snapshot copies, and metadata are encrypted. Access to the data is given by a unique XTS-AES-256 key, one per volume. An external key management server or Onboard Key Manager serves keys to nodes:

- The external key management server is a third-party system in your storage environment that serves keys to nodes using the Key Management Interoperability Protocol (KMIP). It is a best practice to configure external key management servers on a different storage system from your data.
- The Onboard Key Manager is a built-in tool that serves keys to nodes from the same storage system as your data.

Beginning with ONTAP 9.7, aggregate and volume encryption is enabled by default if you have a volume encryption (VE) license and use an onboard or external key manager. Whenever an external or onboard key manager is configured there is a change in how the encryption of data at rest is configured for brand new aggregates and brand new volumes. Brand new aggregates will have NetApp Aggregate Encryption (NAE) enabled by default. Brand new volumes that are not part of an NAE aggregate will have NetApp Volume Encryption (NVE) enabled by default. If a data storage virtual machine (SVM) is configured with its own key-manager using multi-tenant key management, then the volume created for that SVM is automatically configured with NVE.

You can enable encryption on a new or existing volume. NVE supports the full range of storage efficiency features, including deduplication and compression.

If you are using SnapLock, you can enable encryption only on new, empty SnapLock volumes. You cannot enable encryption on an existing SnapLock volume.

You can use NVE on any type of aggregate (HDD, SSD, hybrid, array LUN), with any RAID type, and in any supported ONTAP implementation, including ONTAP Select. You can also use NVE with hardware-based encryption to “double encrypt” data on self-encrypting drives.

AFF A220, AFF A800, FAS2720, FAS2750, and later systems store core dumps on their boot device. When NVE is enabled on these systems, the core dump is also encrypted.

== Aggregate-level encryption

Ordinarily, every encrypted volume is assigned a unique key. When the volume is deleted, the key is deleted with it.

Beginning with ONTAP 9.6, you can use *NetApp Aggregate Encryption (NAE)* to assign keys to the containing aggregate for the volumes to be encrypted. When an encrypted volume is deleted, the keys for the aggregate are preserved. The keys are deleted if the entire aggregate is deleted.

You must use aggregate-level encryption if you plan to perform inline or background aggregate-level deduplication. Aggregate-level deduplication is otherwise not supported by NVE.

Beginning with ONTAP 9.7, aggregate and volume encryption is enabled by default if you have a volume encryption (VE) license and use an onboard or external key manager.

NVE and NAE volumes can coexist on the same aggregate. Volumes encrypted under aggregate-level encryption are NAE volumes by default. You can override the default when you encrypt the volume.

You can use the `volume move` command to convert an NVE volume to an NAE volume, and vice versa. You can replicate an NAE volume to an NVE volume.

You cannot use `secure purge` commands on an NAE volume.

== When to use external key management servers

Although it is less expensive and typically more convenient to use the onboard key manager, you should set up KMIP servers if any of the following are true:

- Your encryption key management solution must comply with Federal Information Processing Standards (FIPS) 140-2 or the OASIS KMIP standard.
- You need a multi-cluster solution, with centralized management of encryption keys.
- Your business requires the added security of storing authentication keys on a system or in a location different from the data.

== Scope of external key management

The scope of external key management determines whether key management servers secure all the SVMs in the cluster or selected SVMs only:

- You can use a *cluster scope* to configure external key management for all the SVMs in the cluster. The cluster administrator has access to every key stored on the servers.
- Beginning with ONTAP 9.6, you can use an *SVM scope* to configure external key management for a named SVM in the cluster. That's best for multitenant environments in which each tenant uses a different SVM (or set of SVMs) to serve data. Only the SVM administrator for a given tenant has access to the keys for that tenant.
- Beginning with ONTAP 9.10.1, you can use [Azure Key Vault and Google Cloud KMS](#) to protect NVE keys only for data vservers.

You can use both scopes in the same cluster. If key management servers have been configured for an SVM, ONTAP uses only those servers to secure keys. Otherwise, ONTAP secures keys with the key management servers configured for the cluster.

A list of validated external key managers is available in the [NetApp Interoperability Matrix Tool \(IMT\)](#). You can find this list by entering the term "key managers" into the IMT's search feature.

== Support details

The following table shows NVE support details:

Resource or feature	Support details
Platforms	AES-NI offload capability required. See the Hardware Universe (HWU) to verify that NVE and NAE are supported for your platform.
Encryption	<p>Beginning with ONTAP 9.7, newly created aggregates and volumes are encrypted by default when you add a volume encryption (VE) license and have an onboard or external key manager configured. If you need to create an unencrypted aggregate, use the following command:</p> <pre>storage aggregate create -encrypt-with-aggr-key false</pre> <p>If you need to create a plain text volume, use the following command:</p> <pre>volume create -encrypt false</pre> <p>Encryption is not enabled by default when:</p> <ul style="list-style-type: none">• VE license is not installed.• Key manager is not configured.• Platform or software does not support encryption.• Hardware encryption is enabled.
ONTAP	All ONTAP implementations. Support for ONTAP Cloud is available in ONTAP 9.5 and later.
Devices	HDD, SSD, hybrid, array LUN.
RAID	RAID0, RAID4, RAID-DP, RAID-TEC.
Volumes	Data volumes and existing root volumes. You cannot encrypt data on an SVM root volume or MetroCluster metadata volumes.
Aggregate-level encryption	<p>Beginning with ONTAP 9.6, NVE supports aggregate-level encryption (NAE):</p> <ul style="list-style-type: none">• You must use aggregate-level encryption if you plan to perform inline or background aggregate-level deduplication.• You cannot rekey an aggregate-level encryption volume.• Secure-purge is not supported on aggregate-level encryption volumes.• In addition to data volumes, NAE supports encryption of SVM root volumes and the MetroCluster metadata volume. NAE does not support encryption of the root volume.

SVM scope	Beginning with ONTAP 9.6, NVE supports SVM scope for external key management only, not for Onboard Key Manager. MetroCluster is supported beginning with ONTAP 9.8.
Storage efficiency	Deduplication, compression, compaction, FlexClone. Clones use the same key as the parent, even after splitting the clone from the parent. You are warned to rekey the split clone.
Replication	<ul style="list-style-type: none"> For volume replication, the destination volume must have been enabled for encryption. Encryption can be configured for the source and unconfigured for the destination, and vice versa. For SVM replication, the destination volume is automatically encrypted, unless the destination does not contain a node that supports volume encryption, in which case replication succeeds, but the destination volume is not encrypted. For MetroCluster configurations, each cluster pulls external key management keys from its configured key servers. OKM keys are replicated to the partner site by the configuration replication service.
Compliance	Beginning with ONTAP 9.2, SnapLock is supported in both Compliance and Enterprise modes, for new volumes only. You cannot enable encryption on an existing SnapLock volume.
FlexGroups	Beginning with ONTAP 9.2, FlexGroups are supported. Destination aggregates must be of the same type as source aggregates, either volume-level or aggregate-level. Beginning with ONTAP 9.5, in-place rekey of FlexGroup volumes is supported.
7-Mode transition	Beginning with 7-Mode Transition Tool 3.3, you can use the 7-Mode Transition Tool CLI to perform copy-based transition to NVE-enabled destination volumes on the clustered system.

Related information

[FAQ - NetApp Volume Encryption and NetApp Aggregate Encryption](#)

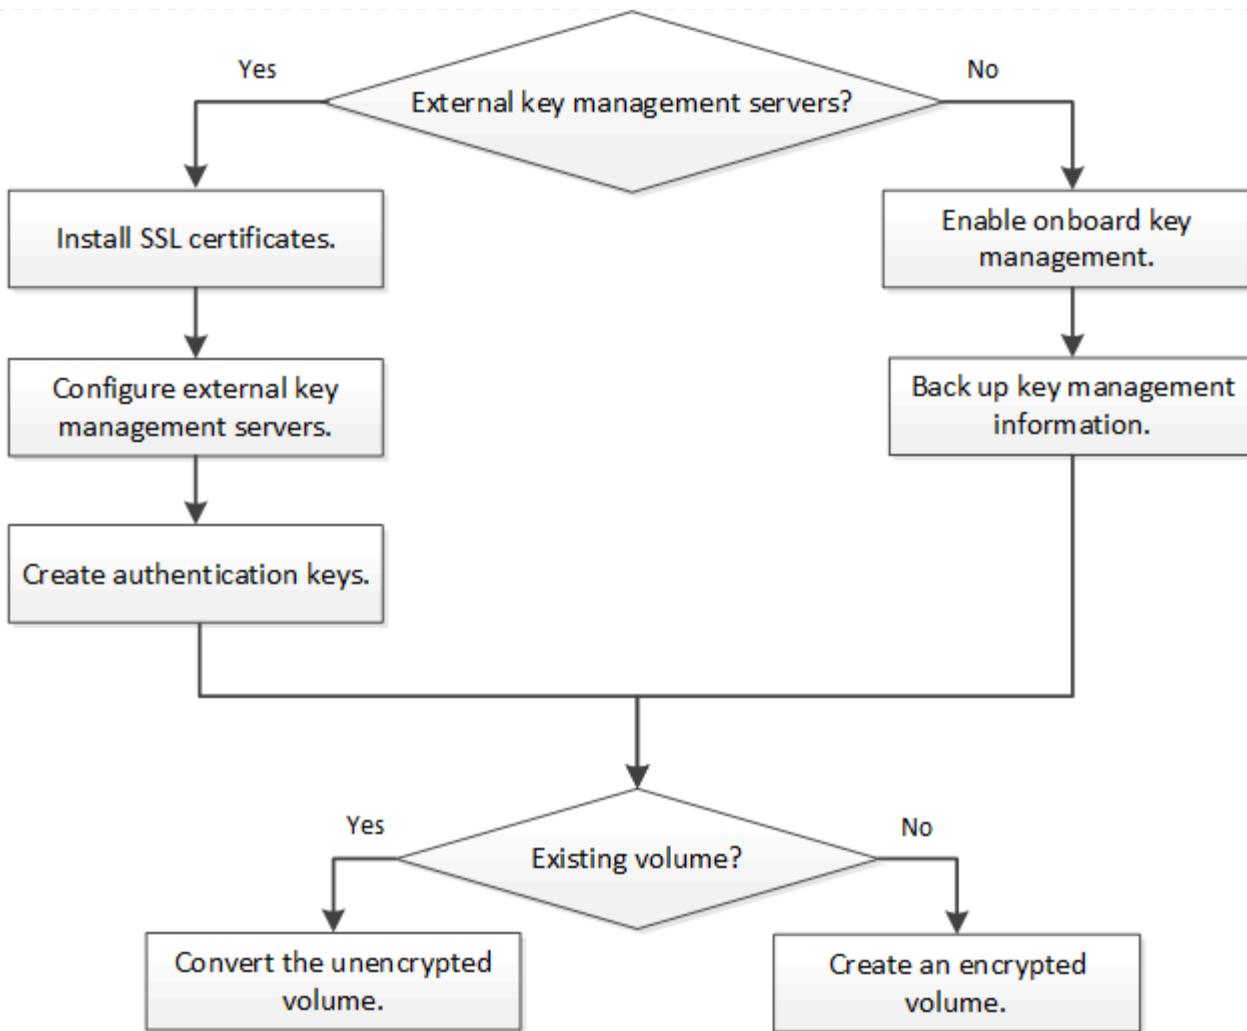

= NetApp Volume Encryption workflow

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.has-audit/./media/

You must configure key management services before you can enable volume encryption. You can enable encryption on a new volume or on an existing volume.

You must install the VE license and configure key management services before you can encrypt data with NVE. Before installing the license, you should [determine whether your ONTAP version supports NVE](#).

= Configure NVE

= Determine whether your cluster version supports NVE

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit./media/

You should determine whether your cluster version supports NVE before you install the license. You can use the `version` command to determine the cluster version.

About this task

The cluster version is the lowest version of ONTAP running on any node in the cluster.

Step

- Determine whether your cluster version supports NVE:

```
version -v
```

NVE is not supported if the command output displays the text “1Ono-DARE” (for “no Data At Rest Encryption”), or if you are using a platform that is not listed in [Support details](#).

The following command determines whether NVE is supported on cluster1.

```
cluster1::> version -v
NetApp Release 9.1.0: Tue May 10 19:30:23 UTC 2016 <1Ono-DARE>
```

The output of 1Ono-DARE indicates that NVE is not supported on your cluster version.

= Install the license
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

A VE license entitles you to use the feature on all nodes in the cluster. You must install the license before you can encrypt data with NVE.

What you'll need

You must be a cluster administrator to perform this task.

About this task

You should have received the VE license key from your sales representative.

Steps

1. Install the VE license for a node:

```
system license add -license-code license_key
```

The following command installs the license with the key AAAAAAAAAAAAAAAAAAAAAA.

```
cluster1::> system license add -license-code
AAAAAAAAAAAAAAAAAAAAA
```

2. Verify that the license is installed by displaying all the licenses on the cluster:

```
system license show
```

For complete command syntax, see the man page for the command.

The following command displays all the licenses on cluster1:

```
cluster1::> system license show
```

The VE license package name is "VE".

= Configure external key management
= Configure external key management overview

```
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/
```

You can use one or more external key management servers to secure the keys that the cluster uses to access encrypted data. An external key management server is a third-party system in your storage environment that serves keys to nodes using the Key Management Interoperability Protocol (KMIP).

For ONTAP 9.1 and earlier versions, node management LIFs must be assigned to ports that are configured with the node management role before you can use the external key manager.

NetApp Volume Encryption (NVE) supports Onboard Key Manager in ONTAP 9.1 and later. Beginning in ONTAP 9.3, NVE supports external key management (KMIP) and Onboard Key Manager. Beginning in ONTAP 9.10.1, you can use [Azure Key Vault or Google Cloud Key Manager Service](#) to protect your NVE keys. Beginning in ONTAP 9.11.1, you can configure multiple external key managers in a cluster. See [Configure clustered key servers](#).

= Install SSL certificates on the cluster

```
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/
```

The cluster and KMIP server use KMIP SSL certificates to verify each other's identity and establish an SSL connection. Before configuring the SSL connection with the KMIP server, you must install the KMIP client SSL certificates for the cluster, and the SSL public certificate for the root certificate authority (CA) of the KMIP server.

What you'll need

- The time must be synchronized on the server creating the certificates, the KMIP server, and the cluster.
- You must have obtained the public SSL KMIP client certificate for the cluster.
- You must have obtained the private key associated with the SSL KMIP client certificate for the cluster.

The SSL KMIP client certificate must not be password-protected.

- You must have obtained the SSL public certificate for the root certificate authority (CA) of the KMIP server.
- In a MetroCluster environment, you must install the KMIP SSL certificate on both clusters.

You can install the client and server certificates on the KMIP server before or after installing the certificates on the cluster.

About this task

In an HA pair, both nodes must use the same public and private KMIP SSL certificates. If you connect multiple HA pairs to the same KMIP server, all nodes in the HA pairs must use the same public and private KMIP SSL certificates.

Steps

1. Install the SSL KMIP client certificates for the cluster:

```
security certificate install -vserver admin_svm_name -type client
```

You are prompted to enter the SSL KMIP public and private certificates.

```
cluster1::> security certificate install -vserver cluster1 -type client
```

2. Install the SSL public certificate for the root certificate authority (CA) of the KMIP server:

```
security certificate install -vserver admin_svm_name -type server-ca
```

```
cluster1::> security certificate install -vserver cluster1 -type server-ca
```

= Enable external key management in ONTAP 9.6 and later (NVE)

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

You can use one or more KMIP servers to secure the keys the cluster uses to access encrypted data. Beginning with ONTAP 9.6, you have the option to configure a separate external key manager to secure the keys that a data SVM uses to access encrypted data.

Beginning in ONTAP 9.11.1, you can add up to 3 secondary key servers per primary key server to create a clustered key server. For more information, see [Configure clustered external key servers](#).

Before you begin

- The KMIP SSL client and server certificates must have been installed.
- You must be a cluster or SVM administrator to perform this task.
- If you want to enable external key management for a MetroCluster environment, MetroCluster must be fully configured before enabling external key management.
- In a MetroCluster environment, you must install the KMIP SSL certificate on both clusters.

About this task

You can connect up to four KMIP servers to a cluster or SVM. A minimum of two servers is recommended for redundancy and disaster recovery.

The scope of external key management determines whether key management servers secure all the SVMs in the cluster or selected SVMs only:

- You can use a *cluster scope* to configure external key management for all the SVMs in the cluster. The cluster administrator has access to every key stored on the servers.

- Beginning with ONTAP 9.6, you can use an SVM scope to configure external key management for a data SVM in the cluster. That's best for multitenant environments in which each tenant uses a different SVM (or set of SVMs) to serve data. Only the SVM administrator for a given tenant has access to the keys for that tenant.
- For multitenant environments, install a license for *MT_EK_MGMT* by using the following command:

```
system license add -license-code <MT_EK_MGMT license code>
```

For complete command syntax, see the man page for the command.

You can use both scopes in the same cluster. If key management servers have been configured for an SVM, ONTAP uses only those servers to secure keys. Otherwise, ONTAP secures keys with the key management servers configured for the cluster.

You can configure onboard key management at the cluster scope and external key management at the SVM scope. You can use the `security key-manager key migrate` command to migrate keys from onboard key management at the cluster scope to external key managers at the SVM scope.

Steps

- Configure key manager connectivity for the cluster:

```
security key-manager external enable -vserver admin_SVM -key-servers
host_name|IP_address:port,... -client-cert client_certificate -server-ca-cert
server_CA_certificates
```

- The `security key-manager external enable` command replaces the `security key-manager setup` command. If you run the command at the cluster login prompt, `admin_SVM` defaults to the admin SVM of the current cluster. You must be the cluster administrator to configure cluster scope. You can run the `security key-manager external modify` command to change the external key management configuration.
- In a MetroCluster environment, if you are configuring external key management for the admin SVM, you must repeat the `security key-manager external enable` command on the partner cluster.

+

The following command enables external key management for `cluster1` with three external key servers. The first key server is specified using its hostname and port, the second is specified using an IP address and the default port, and the third is specified using an IPv6 address and port:

+

```
cluster1::> security key-manager external enable -vserver cluster1 -key  
-servers  
ks1.local:15696,10.0.0.10,[fd20:8b1e:b255:814e:32bd:f35c:832c:5a09]:123  
4 -client-cert AdminVserverClientCert -server-ca-certs  
AdminVserverServerCaCert
```

1. Configure a key manager an SVM:

```
security key-manager external enable -vserver SVM -key-servers  
host_name|IP_address:port,... -client-cert client_certificate -server-ca-cert  
server_CA_certificates
```

- If you run the command at the SVM login prompt, SVM defaults to the current SVM. You must be a cluster or SVM administrator to configure SVM scope. You can run the `security key-manager external modify` command to change the external key management configuration.
- In a MetroCluster environment, if you are configuring external key management for a data SVM, you do not have to repeat the `security key-manager external enable` command on the partner cluster.

+

The following command enables external key management for `svm1` with a single key server listening on the default port 5696:

+

```
svm1::> security key-manager external enable -vserver svm1 -key  
-servers keyserver.svm1.com -client-cert SVM1ClientCert -server-ca  
-certs SVM1ServerCaCert
```

1. Repeat the last step for any additional SVMs.

You can also use the `security key-manager external add-servers` command to configure additional SVMs. The `security key-manager external add-servers` command replaces the `security key-manager add` command. For complete command syntax, see the man page.

1. Verify that all configured KMIP servers are connected:

```
security key-manager external show-status -node node_name
```

The `security key-manager external show-status` command replaces the `security key-manager show -status` command. For complete command syntax, see the man page.

+

```
cluster1::> security key-manager external show-status

Node  Vserver  Key Server                                Status

```

= Enable external key management in ONTAP 9.5 and earlier

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

You can use one or more KMIP servers to secure the keys the cluster uses to access encrypted data. You can connect up to four KMIP servers to a node. A minimum of two servers is recommended for redundancy and disaster recovery.

What you'll need

- The KMIP SSL client and server certificates must have been installed.
- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before you configure an external key manager.
- In a MetroCluster environment, you must install the KMIP SSL certificate on both clusters.

About this task

ONTAP configures KMIP server connectivity for all nodes in the cluster.

Steps

1. Configure key manager connectivity for cluster nodes:

```
security key-manager setup
```

The key manager setup starts.

In a MetroCluster environment, you must run this command on both clusters.

2. Enter the appropriate response at each prompt.

3. Add a KMIP server:

```
security key-manager add -address key_management_server_ipaddress
```

```
cluster1::> security key-manager add -address 20.1.1.1
```

In a MetroCluster environment, you must run this command on both clusters.

4. Add an additional KMIP server for redundancy:

```
security key-manager add -address key_management_server_ipaddress
```

```
cluster1::> security key-manager add -address 20.1.1.2
```

In a MetroCluster environment, you must run this command on both clusters.

5. Verify that all configured KMIP servers are connected:

```
security key-manager show -status
```

For complete command syntax, see the man page.

```
cluster1::> security key-manager show -status
```

Node	Port	Registered Key Manager	Status
cluster1-01	5696	20.1.1.1	available
cluster1-01	5696	20.1.1.2	available
cluster1-02	5696	20.1.1.1	available
cluster1-02	5696	20.1.1.2	available

= Manage keys with a cloud-provider

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

:hardbreaks-option:

Beginning in ONTAP 9.10.1, you can use [Azure Key Vault \(AKV\)](#) and [Google Cloud](#)

[Platform's Key Management Service \(Cloud KMS\)](#) to protect your ONTAP encryption keys in a Azure- or Google Cloud Platform-deployed application.

AKV and Cloud KMS can be used to protect [NetApp Volume Encryption \(NVE\) keys](#) only for data SVMs.

Key management with AKV or Cloud KMS can be enabled with the CLI or the ONTAP REST API.

When using AKV or Cloud KMS, be aware that by default a data SVM LIF is used to communicate with the cloud key management endpoint. A node management network is used to communicate with the cloud provider's authentication services (login.microsoftonline.com for Azure; oauth2.googleapis.com for Cloud KMS). If the cluster network is not configured correctly, the cluster will not properly utilize the key management service.

Prerequisites

- The ONTAP cluster's nodes must support NVE
- Volume Encryption (VE) license installed
- Multi-tenant Encryption Key Management (MTEKM) license installed
- You must be a cluster or SVM administrator

Limitations

- AKV and Cloud KMS are not available for NSE and NAE. [External KMIPs](#) can be used instead
- AKV and Cloud KMS are not available for MetroCluster configurations.
- AKV and Cloud KMS can only be configured on a data SVM

== Enable external key management with the CLI

Enabling external key management depends on the specific key manager you use. If you are enabling AKV in a Cloud Volumes ONTAP, note that there is a separate procedure. Choose the tab of the key manager and environment that suits your needs:

Enable Azure Key Vault for ONTAP

1. Before you begin, you need to obtain the appropriate authentication credentials from your Azure account, either a client secret or certificate.

You must also ensure all nodes in the cluster are healthy. You can check this with the command `cluster show`.

2. Set privileged level to advanced

```
set -priv advanced
```

3. Enable AKV on the SVM

```
security key-manager external azure enable -client-id client_id -tenant-id tenant_id -name key_id -authentication-method {certificate|client-secret}
```

When prompted, enter either the client certificate or client secret from your Azure account.

4. Verify AKV is enabled correctly:

```
security key-manager external azure show vserver SVM_name
```

If the service reachability is not OK, establish the connectivity to the AKV key management service via data SVM LIF.

Enable Cloud KMS with the CLI for ONTAP

1. Before you begin, you need to obtain the private key for the Google Cloud KMS account key file in a JSON format. This can be found in your GCP account.

You must also ensure all nodes in the cluster are healthy. You can check this with the command `cluster show`.

2. Set privileged level to advanced

```
set -priv advanced
```

3. Enable Cloud KMS on the SVM

```
security key-manager external gcp enable -vserver data_svm_name -project-id  
project_id-key-ring-name key_ring_name -key-ring-location key_ring_location  
-key-name key_name
```

When prompted, enter the contents of the JSON file with the Service Account Private Key

4. Verify that Cloud KMS is configured with the correct parameters:

```
security key-manager external gcp show vserver SVM_name
```

The status of `kms_wrapped_key_status` will be "UNKNOWN" if no encrypted volumes have been created.

If the service reachability is not OK, establish the connectivity to the GCP key management service via data SVM LIF.

If one or more encrypted volumes is already configured for a data SVM and the corresponding NVE keys are managed by the admin SVM onboard key manager, those keys should be migrated to the external key management service. To do this with the CLI, run the command:

```
security key-manager key migrate -from-Vserver admin_SVM -to-Vserver data_SVM
```

New encrypted volumes cannot be created for the tenant's data SVM until all NVE keys of the data SVM are successfully migrated.

= Enable onboard key management in ONTAP 9.6 and later (NVE)
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit./media/

You can use the Onboard Key Manager to secure the keys that the cluster uses to access encrypted data. You must enable Onboard Key Manager on each cluster that accesses an encrypted volume or a self-encrypting disk.

What you'll need

- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before you configure an external key manager.

About this task

You must run the `security key-manager onboard sync` command each time you add a node to the cluster.

If you have a MetroCluster configuration you must run `security key-manager onboard enable` on the local cluster first, then run `security key-manager onboard sync` on the remote cluster, using the same passphrase on each.

By default, you are not required to enter the key manager passphrase when a node is rebooted. You can use the `cc-mode-enabled=yes` option to require that users enter the passphrase after a reboot.

For NVE, if you set `cc-mode-enabled=yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted. For `volume create`, you need not specify `-encrypt true`. For `volume move start`, you need not specify `-encrypt-destination true`.

When configuring ONTAP data at rest encryption, to meet the requirements for Commercial Solutions for Classified (CSfC) you must use NSE with NVE and ensure the Onboard Key Manager is enabled in Common Criteria mode. Refer to the [CSfC Solution Brief](#) for more information on CSfC.

When the Onboard Key Manager is enabled in Common Criteria mode (`cc-mode-enabled=yes`), system behavior is changed in the following ways:

- The system monitors for consecutive failed cluster passphrase attempts when operating in Common Criteria mode.

If you fail to enter the correct cluster passphrase at boot, encrypted volumes are not mounted. To correct this, you must reboot the node and enter the correct cluster passphrase. Once booted, the system allows up to 5 consecutive attempts to correctly enter the cluster passphrase in a 24-hour period for any command that requires the cluster passphrase as a parameter. If the limit is reached (for example, you have failed to correctly enter the cluster passphrase 5 times in a row) then you must either wait for the 24-

hour timeout period to elapse, or you must reboot the node, in order to reset the limit.

- System image updates use the NetApp RSA-3072 code signing certificate together with SHA-384 code signed digests to check the image integrity instead of the usual NetApp RSA-2048 code signing certificate and SHA-256 code signed digests.

The upgrade command verifies that the image contents have not been altered or corrupted by checking various digital signatures. The image update process proceeds to the next step if validation succeeds; otherwise, the image update fails. See the “cluster image” man page for information concerning system updates.

The Onboard Key Manager stores keys in volatile memory. Volatile memory contents are cleared when the system is rebooted or halted. Under normal operating conditions, volatile memory contents will be cleared within 30s when a system is halted.

Steps

1. Start the key manager setup:

```
security key-manager onboard enable -cc-mode-enabled yes|no
```

Set cc-mode-enabled=yes to require that users enter the key manager passphrase after a reboot. For NVE, if you set cc-mode-enabled=yes, volumes you create with the volume create and volume move start commands are automatically encrypted. The –cc-mode-enabled option is not supported in MetroCluster configurations. The security key-manager onboard enable command replaces the security key-manager setup command.

+

The following example starts the key manager setup command on cluster1 without requiring that the passphrase be entered after every reboot:

+

```
cluster1::> security key-manager onboard enable
```

```
Enter the cluster-wide passphrase for onboard key management in Vserver  
"cluster1":> <32..256 ASCII characters long text>
```

```
Reenter the cluster-wide passphrase: <32..256 ASCII characters long  
text>
```

1. At the passphrase prompt, enter a passphrase between 32 and 256 characters, or for “cc-mode”, a passphrase between 64 and 256 characters.

If the specified “cc-mode” passphrase is less than 64 characters, there is a five-second delay before the key manager setup operation displays the passphrase prompt again.

1. At the passphrase confirmation prompt, reenter the passphrase.
2. Verify that the authentication keys have been created:

```
security key-manager key query -key-type NSE-AK
```

The security key-manager key query command replaces the security key-manager query key command. For complete command syntax, see the man page.

+

The following example verifies that authentication keys have been created for cluster1:

+

```
cluster1::> security key-manager key query -key-type NSE-AK
    Vserver: cluster1
    Key Manager: onboard
        Node: node1

000000000

```

After you finish

Copy the passphrase to a secure location outside the storage system for future use.

All key management information is automatically backed up to the replicated database (RDB) for the cluster. You should also back up the information manually for use in case of a disaster.

= Enable onboard key management in ONTAP 9.5 and earlier (NVE)

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit./media/

You can use the Onboard Key Manager to secure the keys that the cluster uses to access encrypted data. You must enable Onboard Key Manager on each cluster that accesses an encrypted volume or a self-encrypting disk.

What you'll need

- If you are using NSE with an external key management (KMIP) server, you must have deleted the external key manager database.

[Transitioning to onboard key management from external key management](#)

- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before you configure the Onboard Key Manager.

About this task

You must run the `security key-manager setup` command each time you add a node to the cluster.

If you have a MetroCluster configuration, review these guidelines:

- In ONTAP 9.5, you must run `security key-manager setup` on the local cluster and `security key-manager setup -sync-metrocluster-config yes` on the remote cluster, using the same passphrase on each.
- Prior to ONTAP 9.5, you must run `security key-manager setup` on the local cluster, wait approximately 20 seconds, and then run `security key-manager setup` on the remote cluster, using the same passphrase on each.

By default, you are not required to enter the key manager passphrase when a node is rebooted. Beginning with ONTAP 9.4, you can use the `-enable-cc-mode yes` option to require that users enter the passphrase after a reboot.

For NVE, if you set `-enable-cc-mode yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted. For `volume create`, you need not specify `-encrypt true`. For `volume move start`, you need not specify `-encrypt-destination true`.

After a failed passphrase attempt, you must reboot the node again.

Steps

1. Start the key manager setup:

```
security key-manager setup -enable-cc-mode yes|no
```

Beginning with ONTAP 9.4, you can use the `-enable-cc-mode yes` option to require that users enter the key manager passphrase after a reboot. For NVE, if you set `-enable-cc-mode yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted.

+

The following example starts setting up the key manager on cluster1 without requiring that the passphrase be entered after every reboot:

+

```
cluster1::> security key-manager setup
Welcome to the key manager setup wizard, which will lead you through
the steps to add boot information.

...
Would you like to use onboard key-management? {yes, no} [yes]:
Enter the cluster-wide passphrase:      <32..256 ASCII characters long
text>
Reenter the cluster-wide passphrase:    <32..256 ASCII characters long
text>
```

1. Enter yes at the prompt to configure onboard key management.
2. At the passphrase prompt, enter a passphrase between 32 and 256 characters, or for “cc-mode”, a passphrase between 64 and 256 characters.

If the specified “cc-mode” passphrase is less than 64 characters, there is a five-second delay before the key manager setup operation displays the passphrase prompt again.

1. At the passphrase confirmation prompt, reenter the passphrase.

2. Verify that keys are configured for all nodes:

```
security key-manager key show
```

For the complete command syntax, see the man page.

```
cluster1::> security key-manager key show

Node: node1
Key Store: onboard
Key ID
Used By
-----
-----
000000000000000020000000000010059851742AF2703FC91369B7DB47C4722

```

After you finish

Copy the passphrase to a secure location outside the storage system for future use.

All key management information is automatically backed up to the replicated database (RDB) for the cluster.

Whenever you configure the Onboard Key Manager passphrase, you should also back up the information manually to a secure location outside the storage system for use in case of a disaster. See [Back up onboard key management information manually](#).

= Enable onboard key management in newly added nodes

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

You can use the Onboard Key Manager to secure the keys that the cluster uses to

access encrypted data. You must enable Onboard Key Manager on each cluster that accesses an encrypted volume or a self-encrypting disk.

For ONTAP 9.5 and earlier, you must run the `security key-manager setup` command each time you add a node to the cluster.

For ONTAP 9.6 and later, you must run the `security key-manager sync` command each time you add a node to the cluster.

If you add a node to a cluster that has onboard key management configured, you will run this command to refresh the missing keys.

If you have a MetroCluster configuration, review these guidelines:

- Beginning with ONTAP 9.6, you must run `security key-manager onboard enable` on the local cluster first, then run `security key-manager onboard sync` on the remote cluster, using the same passphrase on each.
- In ONTAP 9.5, you must run `security key-manager setup` on the local cluster and `security key-manager setup -sync-metrocluster-config yes` on the remote cluster, using the same passphrase on each.
- Prior to ONTAP 9.5, you must run `security key-manager setup` on the local cluster, wait approximately 20 seconds, and then run `security key-manager setup` on the remote cluster, using the same passphrase on each.

By default, you are not required to enter the key manager passphrase when a node is rebooted. Beginning with ONTAP 9.4, you can use the `-enable-cc-mode yes` option to require that users enter the passphrase after a reboot.

For NVE, if you set `-enable-cc-mode yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted. For `volume create`, you need not specify `-encrypt true`. For `volume move start`, you need not specify `-encrypt-destination true`.

After a failed passphrase attempt, you must reboot the node again.

= Encrypt volume data with NVE

= Encrypt volume data with NVE overview

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

Beginning with ONTAP 9.7, aggregate and volume encryption is enabled by default when you have the VE license and onboard or external key management. For ONTAP 9.6 and earlier, you can enable encryption on a new volume or on an existing volume. You must have installed the VE license and enabled key management before you can enable volume encryption. NVE is FIPS-140-2 level 1 compliant.

= Enable aggregate-level encryption with VE license

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

Beginning with ONTAP 9.7, newly created aggregates and volumes are encrypted by default when you have the VE license and onboard or external key management.

Beginning with ONTAP 9.6, you can use aggregate-level encryption to assign keys to the containing aggregate for the volumes to be encrypted.

What you'll need

You must be a cluster administrator to perform this task.

About this task

You must use aggregate-level encryption if you plan to perform inline or background aggregate-level deduplication. Aggregate-level deduplication is otherwise not supported by NVE.

An aggregate enabled for aggregate-level encryption is called an *NAE aggregate* (for NetApp Aggregate Encryption). All volumes in an NAE aggregate must be encrypted with NAE or NVE encryption. With aggregate-level encryption, volumes you create in the aggregate are encrypted with NAE encryption by default. You can override the default to use NVE encryption instead.

Plain text volumes are not supported in NAE aggregates.

Steps

1. Enable or disable aggregate-level encryption:

To...	Use this command...
Create an NAE aggregate with ONTAP 9.7 or later	<code>storage aggregate create -aggregate aggregate_name -node node_name</code>
Create an NAE aggregate with ONTAP 9.6	<code>storage aggregate create -aggregate aggregate_name -node node_name -encrypt-with-aggr-key true</code>

Convert a non-NAE aggregate to an NAE aggregate	<pre>storage aggregate modify -aggregate aggregate_name -node node_name -encrypt-with-aggr-key true</pre>
Convert an NAE aggregate to a non-NAE aggregate	<pre>storage aggregate modify -aggregate aggregate_name -node node_name -encrypt-with-aggr-key false</pre>

For complete command syntax, see the man pages.

The following command enables aggregate-level encryption on `aggr1`:

- ONTAP 9.7 or later:

```
cluster1::> storage aggregate create -aggregate aggr1
```

- ONTAP 9.6 or earlier:

```
cluster1::> storage aggregate create -aggregate aggr1 -encrypt-with-aggr-key true
```

2. Verify that the aggregate is enabled for encryption:

```
storage aggregate show -fields encrypt-with-aggr-key
```

For complete command syntax, see the man page.

The following command verifies that `aggr1` is enabled for encryption:

```
cluster1::> storage aggregate show -fields encrypt-with-aggr-key
aggregate          encrypt-aggr-key
-----
aggr0_vsim4        false
aggr1              true
2 entries were displayed.
```

After you finish

Run the `volume create` command to create the encrypted volumes.

If you are using a KMIP server to store the encryption keys for a node, ONTAP automatically “pushes” an encryption key to the server when you encrypt a volume.

= Enable encryption on a new volume
:icons: font
:relative_path: ./encryption-at-rest/

You can use the `volume create` command to enable encryption on a new volume.

About this task

You can encrypt volumes using NetApp Volume Encryption (NVE) and, beginning with ONTAP 9.6, NetApp Aggregate Encryption (NAE). To learn more about NAE and NVE, refer to the [volume encryption overview](#).

The procedure to enable encryption on a new volume in ONTAP varies based on the version of ONTAP you are using and your specific configuration:

- Beginning with ONTAP 9.4, if you enable `cc-mode` when you set up the Onboard Key Manager, volumes you create with the `volume create` command are automatically encrypted, whether or not you specify `-encrypt true`.
- In ONTAP 9.6 and earlier releases, you must use `-encrypt true` with `volume create` commands to enable encryption (provided you did not enable `cc-mode`).
- If you want to create an NAE volume in ONTAP 9.6, you must enable NAE at the aggregate level. Refer to [Enable aggregate-level encryption with the VE license](#) for more details on this task.
- Beginning with ONTAP 9.7, newly created volumes are encrypted by default when you have the VE license and onboard or external key management. By default, new volumes created in an NAE aggregate will be of type NAE rather than NVE.
 - In ONTAP 9.7 and later releases, if you add `-encrypt true` to the `volume create` command to create a volume in an NAE aggregate, the volume will have NVE encryption instead of NAE. All volumes in an NAE aggregate must be encrypted with either NVE or NAE.

Plaintext volumes are not supported in NAE aggregates.

Steps

1. Create a new volume and specify whether encryption is enabled on the volume. If the new volume is in an NAE aggregate, by default the volume will be an NAE volume:

To create...	Use this command...
An NAE volume	<code>volume create -vserver SVM_name -volume volume_name -aggregate aggregate_name</code>
An NVE volume	<code>volume create -vserver SVM_name -volume volume_name -aggregate aggregate_name -encrypt true</code>

In ONTAP 9.6 and earlier where NAE is not supported, `-encrypt true` specifies that the volume should be encrypted with NVE. In ONTAP 9.7 and later where volumes are created in NAE aggregates, `-encrypt true` overrides the default encryption type of NAE to create an NVE volume instead.

A plain text volume

```
volume create -vserver SVM_name -volume volume_name  
-aggregate aggregate_name -encrypt false
```

For complete command syntax, refer to the command reference page for `volume create`.

2. Verify that volumes are enabled for encryption:

```
volume show -is-encrypted true
```

For complete command syntax, see the [command reference](#).

Result

If you are using a KMIP server to store the encryption keys for a node, ONTAP automatically "pushes" an encryption key to the server when you encrypt a volume.

= Enable encryption on an existing volume with the `volume encryption conversion start` command

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit./media/

Beginning with ONTAP 9.3, you can use the `volume encryption conversion start` command to enable encryption of an existing volume "in place," without having to move the volume to a different location.

About this task

Once you start a conversion operation, it must complete. If you encounter a performance issue during the operation, you can run the `volume encryption conversion pause` command to pause the operation, and the `volume encryption conversion resume` command to resume the operation.

You cannot use `volume encryption conversion start` to convert a SnapLock volume.

Steps

1. Enable encryption on an existing volume:

```
volume encryption conversion start -vserver SVM_name -volume volume_name
```

For complete command syntax, see the man page for the command.

The following command enables encryption on the existing volume `vol1`:

```
cluster1::> volume encryption conversion start -vserver vs1 -volume vol1
```

The system creates an encryption key for the volume. The data on the volume is encrypted.

2. Verify the status of the conversion operation:

```
volume encryption conversion show
```

For complete command syntax, see the man page for the command.

The following command displays the status of the conversion operation:

```
cluster1::> volume encryption conversion show
```

Vserver	Volume	Start Time	Status
vs1	vol1	9/18/2017 17:51:41	Phase 2 of 2 is in progress.

3. When the conversion operation is complete, verify that the volume is enabled for encryption:

```
volume show -is-encrypted true
```

For complete command syntax, see the man page for the command.

The following command displays the encrypted volumes on `cluster1`:

```
cluster1::> volume show -is-encrypted true
```

Vserver	Volume	Aggregate	State	Type	Size	Available	Used
vs1	vol1	aggr2	online	RW	200GB	160.0GB	20%

Result

If you are using a KMIP server to store the encryption keys for a node, ONTAP automatically “pushes” an encryption key to the server when you encrypt a volume.

= Enable encryption on an existing volume with the volume move start command

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit./media/

You can use the `volume move start` command to enable encryption by moving an existing volume. You must use `volume move start` in ONTAP 9.2 and earlier. You can use the same aggregate or a different aggregate.

What you'll need

You must be a cluster administrator to perform this task, or an SVM administrator to whom the cluster administrator has delegated authority.

Delegating authority to run the volume move command

About this task

Beginning with ONTAP 9.8, you can use `volume move start` to enable encryption on a SnapLock or FlexGroup volume.

Beginning with ONTAP 9.4, if you enable “cc-mode” when you set up the Onboard Key Manager, volumes you create with the `volume move start` command are automatically encrypted. You need not specify `-encrypt-destination true`.

Beginning with ONTAP 9.6, you can use aggregate-level encryption to assign keys to the containing aggregate for the volumes to be moved. A volume encrypted with a unique key is called an *NVE volume*. A volume encrypted with an aggregate-level key is called an *NAE volume* (for NetApp Aggregate Encryption). Plaintext volumes are not supported in NAE aggregates.

Steps

1. Move an existing volume and specify whether encryption is enabled on the volume:

To convert...	Use this command...
A plaintext volume to an NVE volume	<code>volume move start -vserver SVM_name -volume volume_name -destination-aggregate aggregate_name -encrypt-destination true</code>
An NVE or plaintext volume to an NAE volume (assuming aggregate-level encryption is enabled on the destination)	<code>volume move start -vserver SVM_name -volume volume_name -destination-aggregate aggregate_name -encrypt-with-aggr-key true</code>
An NAE volume to an NVE volume	<code>volume move start -vserver SVM_name -volume volume_name -destination-aggregate aggregate_name -encrypt-with-aggr-key false</code>
An NAE volume to a plaintext volume	<code>volume move start -vserver SVM_name -volume volume_name -destination-aggregate aggregate_name -encrypt-destination false -encrypt-with-aggr-key false</code>

An NVE volume to a plaintext volume

```
volume move start -vserver SVM_name -volume  
volume_name -destination-aggregate  
aggregate_name -encrypt-destination false
```

For complete command syntax, see the man page for the command.

The following command converts a plaintext volume named `vol1` to an NVE volume:

```
cluster1::> volume move start -vserver vs1 -volume vol1 -destination  
-aggregate aggr2 -encrypt-destination true
```

Assuming aggregate-level encryption is enabled on the destination, the following command converts an NVE or plaintext volume named `vol1` to an NAE volume:

```
cluster1::> volume move start -vserver vs1 -volume vol1 -destination  
-aggregate aggr2 -encrypt-with-aggr-key true
```

The following command converts an NAE volume named `vol2` to an NVE volume:

```
cluster1::> volume move start -vserver vs1 -volume vol2 -destination  
-aggregate aggr2 -encrypt-with-aggr-key false
```

The following command converts an NAE volume named `vol2` to a plaintext volume:

```
cluster1::> volume move start -vserver vs1 -volume vol2 -destination  
-aggregate aggr2 -encrypt-destination false -encrypt-with-aggr-key  
false
```

The following command converts an NVE volume named `vol2` to a plaintext volume:

```
cluster1::> volume move start -vserver vs1 -volume vol2 -destination  
-aggregate aggr2 -encrypt-destination false
```

2. View the encryption type of cluster volumes:

```
volume show -fields encryption-type none|volume|aggregate
```

The `encryption-type` field is available in ONTAP 9.6 and later.

For complete command syntax, see the man page for the command.

The following command displays the encryption type of volumes in `cluster2`:

```
cluster2::> volume show -fields encryption-type

vserver    volume    encryption-type
-----  -----
vs1        vol1      none
vs2        vol2      volume
vs3        vol3      aggregate
```

3. Verify that volumes are enabled for encryption:

```
volume show -is-encrypted true
```

For complete command syntax, see the man page for the command.

The following command displays the encrypted volumes on cluster2:

```
cluster2::> volume show -is-encrypted true

Vserver    Volume    Aggregate    State    Type    Size    Available    Used
-----  -----  -----  -----  -----  -----  -----  -----
vs1        vol1      aggr2       online    RW     200GB    160.0GB   20%
```

Result

If you are using a KMIP server to store the encryption keys for a node, ONTAP automatically “pushes” an encryption key to the server when you encrypt a volume.

= Enable node root volume encryption

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit./media/

Beginning with ONTAP 9.8, you can use NetApp Volume Encryption to protect the root volume of your node.

What you'll need

- Your system must be using an HA configuration.

Root volume encryption is not supported on single node configurations.

- Your node root volume must already be created.
- Your system must have an onboard key manager or an external key management server using the Key Management Interoperability Protocol (KMIP).

This procedure applies to the node root volume. It does not apply to SVM root volumes. SVM root volumes can be protected through aggregate-level encryption.

Once root volume encryption begins, it must complete. You cannot pause the operation. Once encryption is complete, you cannot assign a new key to the root volume and you cannot perform a secure-purge operation.

Steps

1. Encrypt the root volume:

```
volume encryption conversion start -vserver SVM_name -volume root_vol_name
```

2. Verify the status of the conversion operation:

```
volume encryption conversion show
```

3. When the conversion operation is complete, verify that the volume is encrypted:

```
volume show -fields
```

The following shows example output for an encrypted volume.

```
::> volume show -vserver xyz -volume vol0 -fields is-encrypted
vserver      volume is-encrypted
-----
xyz          vol0    true
```

= Configure NetApp hardware-based encryption

= Configure NetApp hardware-based encryption overview

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit./media/

NetApp hardware-based encryption supports full-disk encryption (FDE) of data as it is written. The data cannot be read without an encryption key stored on the firmware. The encryption key, in turn, is accessible only to an authenticated node.

== Understanding NetApp hardware-based encryption

A node authenticates itself to a self-encrypting drive using an authentication key retrieved from an external key management server or Onboard Key Manager:

- The external key management server is a third-party system in your storage environment that serves keys to nodes using the Key Management Interoperability Protocol (KMIP). It is a best practice to configure external key management servers on a different storage system from your data.
- The Onboard Key Manager is a built-in tool that serves authentication keys to nodes from the same storage system as your data.

You can use NetApp Volume Encryption with hardware-based encryption to “double encrypt” data on self-encrypting drives.

 If an HA pair is using encrypting SAS or NVMe drives (SED, NSE, FIPS), you must follow the instructions in the topic [Returning a FIPS drive or SED to unprotected mode](#) for all drives within the HA pair prior to initializing the system (boot options 4 or 9). Failure to do this may result in future data loss if the drives are repurposed.

== Supported self-encrypting drive types

Two types of self-encrypting drives are supported:

- Self-encrypting FIPS-certified SAS or NVMe drives are supported on all FAS and AFF systems. These drives, called *FIPS drives*, conform to the requirements of Federal Information Processing Standard Publication 140-2, level 2. The certified capabilities enable protections in addition to encryption, such as preventing denial-of-service attacks on the drive. FIPS drives cannot be mixed with other types of drives on the same node or HA pair.
- Beginning with ONTAP 9.6, self-encrypting NVMe drives that have not undergone FIPS testing are supported on AFF A800, A320, and later systems. These drives, called *SEDs*, offer the same encryption capabilities as FIPS drives, but can be mixed with non-encrypting drives on the same node or HA pair.
- All FIPS validated drives use a firmware cryptographic module that has been through FIPS validation. The FIPS drive cryptographic module does not use any keys that are generated outside of the drive (the authentication passphrase that is input to the drive is used by the drive's firmware cryptographic module to obtain a key encryption key).

Non-encrypting drives are drives that are not SEDs or FIPS drives.

== When to use external key management

Although it is less expensive and typically more convenient to use the onboard key manager, you should use external key management if any of the following are true:

- Your organization's policy requires a key management solution that uses a FIPS 140-2 Level 2 (or higher) cryptographic module.
- You need a multi-cluster solution, with centralized management of encryption keys.
- Your business requires the added security of storing authentication keys on a system or in a location different from the data.

== Support details

The following table shows important hardware encryption support details. See the Interoperability Matrix for the latest information about supported KMIP servers, storage systems, and disk shelves.

Resource or feature	Support details
Non-homogeneous disk sets	<ul style="list-style-type: none">• FIPS drives cannot be mixed with other types of drives on the same node or HA pair. Conforming HA pairs can coexist with non-conforming HA pairs in the same cluster.• SEDs can be mixed with non-encrypting drives on the same node or HA pair.

Drive type	<ul style="list-style-type: none"> FIPS drives can be SAS or NVMe drives. SEDs must be NVMe drives.
10 Gb network interfaces	Beginning with ONTAP 9.3, KMIP key management configurations support 10 Gb network interfaces for communications with external key management servers.
Ports for communication with the key management server	Beginning with ONTAP 9.3, you can use any storage controller port for communication with the key management server. Otherwise, you should use port e0M for communication with key management servers. Depending on the storage controller model, certain network interfaces might not be available during the boot process for communication with key management servers.
MetroCluster (MCC)	<ul style="list-style-type: none"> NVMe drives support MCC. SAS drives do not support MCC.

= Hardware-based encryption workflow

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit./media/

You must configure key management services before the cluster can authenticate itself to the self-encrypting drive. You can use an external key management server or an onboard key manager.

= Configure external key management

= Configure external key management overview

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit./media/

You can use one or more external key management servers to secure the keys that the cluster uses to access encrypted data. An external key management server is a third-party system in your storage environment that serves keys to nodes using the Key Management Interoperability Protocol (KMIP).

For ONTAP 9.1 and earlier versions, node management LIFs must be assigned to ports that are configured with the node management role before you can use the external key manager.

NetApp Volume Encryption (NVE) can be implemented with Onboard Key Manager in ONTAP 9.1 and later. In ONTAP 9.3 and later, NVE can be implemented with external key management (KMIP) and Onboard Key Manager. Beginning in ONTAP 9.11.1, you can configure multiple external key managers in a cluster. See [Configure clustered key servers](#).

= Collect network information in ONTAP 9.2 and earlier

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit./media/

If you are using ONTAP 9.2 or earlier, you should fill out the network configuration

worksheet before enabling external key management.

Beginning with ONTAP 9.3, the system discovers all needed network information automatically.

Item	Notes	Value
Key management network interface name		
Key management network interface IP address	IP address of node management LIF, in IPv4 or IPv6 format	
Key management network interface IPv6 network prefix length	If you are using IPv6, the IPv6 network prefix length	
Key management network interface subnet mask		
Key management network interface gateway IP address		
IPv6 address for the cluster network interface	Required only if you are using IPv6 for the key management network interface	
Port number for each KMIP server	Optional. The port number must be the same for all KMIP servers. If you do not provide a port number, it defaults to port 5696, which is the Internet Assigned Numbers Authority (IANA) assigned port for KMIP.	
Key tag name	Optional. The key tag name is used to identify all keys belonging to a node. The default key tag name is the node name.

[NetApp Technical Report 4074: NetApp Storage Encryption Preinstallation Requirements and Procedures for SafeNet KeySecure](#)

= Install SSL certificates on the cluster

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/./nas-audit/..../media/

The cluster and KMIP server use KMIP SSL certificates to verify each other's identity and establish an SSL connection. Before configuring the SSL connection with the KMIP server, you must install the KMIP client SSL certificates for the cluster, and the

SSL public certificate for the root certificate authority (CA) of the KMIP server.

What you'll need

- The time must be synchronized on the server creating the certificates, the KMIP server, and the cluster.
- You must have obtained the public SSL KMIP client certificate for the cluster.
- You must have obtained the private key associated with the SSL KMIP client certificate for the cluster.

The SSL KMIP client certificate must not be password-protected.

- You must have obtained the SSL public certificate for the root certificate authority (CA) of the KMIP server.
- In a MetroCluster environment, you must install the KMIP SSL certificate on both clusters.

You can install the client and server certificates on the KMIP server before or after installing the certificates on the cluster.

About this task

In an HA pair, both nodes must use the same public and private KMIP SSL certificates. If you connect multiple HA pairs to the same KMIP server, all nodes in the HA pairs must use the same public and private KMIP SSL certificates.

Steps

1. Install the SSL KMIP client certificates for the cluster:

```
security certificate install -vserver admin_svm_name -type client
```

You are prompted to enter the SSL KMIP public and private certificates.

```
cluster1::> security certificate install -vserver cluster1 -type client
```

2. Install the SSL public certificate for the root certificate authority (CA) of the KMIP server:

```
security certificate install -vserver admin_svm_name -type server-ca
```

```
cluster1::> security certificate install -vserver cluster1 -type server-ca
```

= Enable external key management in ONTAP 9.6 and later (HW-based)

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

You can use one or more KMIP servers to secure the keys the cluster uses to access encrypted data. You can connect up to four KMIP servers to a node. A minimum of two servers is recommended for redundancy and disaster recovery.

Beginning in ONTAP 9.11.1, you can add up to 3 secondary key servers per primary key server to create a clustered key server. For more information, see [Configure clustered external key servers](#).

Before you begin

- The KMIP SSL client and server certificates must have been installed.
- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before you configure an external key manager.
- In a MetroCluster environment, you must install the KMIP SSL certificate on both clusters.

Steps

1. Configure key manager connectivity for the cluster:

```
security key-manager external enable -vserver admin_SVM -key-servers
host_name|IP_address:port,... -client-cert client_certificate -server-ca
-cert server_CA_certificates
```

- The `security key-manager external enable` command replaces the `security key-manager setup` command. You can run the `security key-manager external modify` command to change the external key management configuration. For complete command syntax, see the man pages.

- In a MetroCluster environment, if you are configuring external key management for the admin SVM, you must repeat the `security key-manager external enable` command on the partner cluster.

+

The following command enables external key management for `cluster1` with three external key servers. The first key server is specified using its hostname and port, the second is specified using an IP address and the default port, and the third is specified using an IPv6 address and port:

+

```
cluster1::> security key-manager external enable -key-servers  
ks1.local:15696,10.0.0.10,[fd20:8b1e:b255:814e:32bd:f35c:832c:5a09]:123  
4 -client-cert AdminVserverClientCert -server-ca-certs  
AdminVserverServerCaCert
```

1. Verify that all configured KMIP servers are connected:

```
security key-manager external show-status -node node_name -vserver SVM -key  
-server host_name|IP_address:port -key-server-status available|not-  
responding|unknown
```

The `security key-manager external show-status` command replaces the `security key-manager show -status` command. For complete command syntax, see the man page.

+

```
cluster1::> security key-manager external show-status

Node  Vserver  Key Server                                Status
----  -----  -----
-----  
node1
    cluster1
        10.0.0.10:5696                               available
        fd20:8b1e:b255:814e:32bd:f35c:832c:5a09:1234   available
        ks1.local:15696                                available  
node2
    cluster1
        10.0.0.10:5696                               available
        fd20:8b1e:b255:814e:32bd:f35c:832c:5a09:1234   available
        ks1.local:15696                                available  
6 entries were displayed.
```

= Enable external key management in ONTAP 9.5 and earlier

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

You can use one or more KMIP servers to secure the keys the cluster uses to access encrypted data. You can connect up to four KMIP servers to a node. A minimum of two servers is recommended for redundancy and disaster recovery.

What you'll need

- The KMIP SSL client and server certificates must have been installed.
- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before you configure an external key manager.
- In a MetroCluster environment, you must install the KMIP SSL certificate on both clusters.

About this task

ONTAP configures KMIP server connectivity for all nodes in the cluster.

Steps

1. Configure key manager connectivity for cluster nodes:

```
security key-manager setup
```

The key manager setup starts.

In a MetroCluster environment, you must run this command on both clusters.

2. Enter the appropriate response at each prompt.

3. Add a KMIP server:

```
security key-manager add -address key_management_server_ipaddress
```

```
cluster1::> security key-manager add -address 20.1.1.1
```

In a MetroCluster environment, you must run this command on both clusters.

4. Add an additional KMIP server for redundancy:

```
security key-manager add -address key_management_server_ipaddress
```

```
cluster1::> security key-manager add -address 20.1.1.2
```

In a MetroCluster environment, you must run this command on both clusters.

5. Verify that all configured KMIP servers are connected:

```
security key-manager show -status
```

For complete command syntax, see the man page.

```
cluster1::> security key-manager show -status
```

Node	Port	Registered Key Manager	Status
cluster1-01	5696	20.1.1.1	available
cluster1-01	5696	20.1.1.2	available
cluster1-02	5696	20.1.1.1	available
cluster1-02	5696	20.1.1.2	available

= Configure clustered external key servers

:hardbreaks:

:icons: font

:linkattrs:

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.has-audit/../media/

Beginning in ONTAP 9.11.1, you can configure connectivity to clustered external key management servers on an SVM. With clustered key servers, you can designate primary and secondary key servers on a SVM. When registering keys, ONTAP will first attempt to access a primary key server before sequentially attempting to access secondary servers until the operation completes successfully, preventing duplication

of keys.

External key servers can be used for NSE, NVE, NAE, and SED keys. An SVM can support up to four primary external KMIP servers. Each primary server can support up to three secondary key servers.

== Before you begin

- * [KMIP key management is already enabled for the SVM.](#)
- * This process only supports key servers that use KMIP. For a list of supported key servers, check the [NetApp Interoperability Matrix Tool](#).
- * All nodes in the cluster must be running ONTAP 9.11.1 or later.
- * The order of servers list arguments in the `-secondary-key-servers` parameter reflects the access order of the external key management (KMIP) servers.

== Create a clustered key server

The configuration procedure depends on whether or not you have configured a primary key server.

1. Confirm that no key management has been enabled for the cluster:

```
security key-manager external show -vserver vserver_name
```

If the SVM already has the maximum of four primary key servers enabled, you must remove one of the existing primary key servers before adding a new one.

2. Enable the primary key manager:

```
security key-manager external enable -vserver vserver_name -key-servers  
server_ip -client-cert client_cert_name -server-ca-certs server_ca_cert_names
```

3. Modify the primary key server to add secondary key servers. The `-secondary-key-servers` parameter accepts a comma-separated list of up to three key servers.

```
security key-manager external modify-server -vserver vserver_name -key-servers  
primary_key_server -secondary-key-servers list_of_key_servers
```

1. Modify the primary key server to add secondary key servers. The `-secondary-key-servers` parameter accepts a comma-separated list of up to three key servers.

```
security key-manager external modify-server -vserver vserver_name -key-servers  
primary_key_server -secondary-key-servers list_of_key_servers
```

For more information about secondary key servers, see [\[mod-secondary\]](#).

== Modify clustered key servers

You can modify external key servers clusters by changing the status (primary or secondary) of particular key servers, add and removing secondary key servers, or by changing the access order of secondary key servers.

==== Converting primary and secondary key servers

To convert a primary key server into a secondary key server, you must first remove it from the SVM with the security key-manager external remove-servers command.

To convert a secondary key server into a primary key server, you must first remove the secondary key server from its existing primary key server. See [\[mod-secondary\]](#). If you convert a secondary key server to a primary server while removing an existing key, attempting to add a new server before completing the removal and conversion can result in the the duplication of keys.

==== Modifying secondary key servers

Secondary key servers are managed with the -secondary-key-servers parameter of the security key-manager external modify-server command. The -secondary-key-servers parameter accepts a comma-separated list. The specified order of the secondary key servers in the list determines the access sequence for the secondary key servers. The access order can be modified by running the command security key-manager external modify-server with the secondary key servers entered in a different sequence.

To remove a secondary key server, the -secondary-key-servers arguments should include the key servers you want to keep while omitting the one to be removed. To remove all secondary key servers, use the argument -, signifying none.

For additional information, refer to the security key-manager external page in the [ONTAP command reference](#).

= Create authentication keys in ONTAP 9.6 and later

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.has-audit/./media/

You can use the security key-manager key create command to create the authentication keys for a node and store them on the configured KMIP servers.

What you'll need

You must be a cluster administrator to perform this task.

About this task

If your security setup requires you to use different keys for data authentication and FIPS 140-2 authentication, you should create a separate key for each. If that is not the case, you can use the same authentication key for FIPS compliance that you use for data access.

ONTAP creates authentication keys for all nodes in the cluster.

- This command is not supported when Onboard Key Manager is enabled. However, two authentication keys are created automatically when Onboard Key Manager is enabled. The keys can be viewed with the following command:

```
security key-manager key query -key-type NSE-AK
```

- You receive a warning if the configured key management servers are already storing more than 128 authentication keys.
- You can use the security key-manager key delete command to delete any unused keys. The security key-manager key delete command fails if the given key is currently in use by ONTAP. (You must have privileges greater than “admin” to use this command.)

In a MetroCluster environment, before you delete a key, you must make sure that the key is not in use on the partner cluster. You can use the following commands on the partner cluster to check that the key is not in use:

- storage encryption disk show -data-key-id *key-id*
- storage encryption disk show -fips-key-id *key-id*

Steps

1. Create the authentication keys for cluster nodes:

```
security key-manager key create -key-tag passphrase_label -prompt-for-key  
true|false
```

Setting prompt-for-key=true causes the system to prompt the cluster administrator for the passphrase to use when authenticating encrypted drives. Otherwise, the system automatically generates a 32-byte passphrase. The security key-manager key create command replaces the security key-manager create-key command. For complete command syntax, see the man page.

+

The following example creates the authentication keys for cluster1, automatically generating a 32-byte passphrase:

+

```
cluster1::> security key-manager key create  
Key ID:  
00000000000000000000200000000001006268333f870860128fbe17d393e5083b0000000  
00000000
```

1. Verify that the authentication keys have been created:

```
security key-manager key query -node node
```

The security key-manager key query command replaces the security key-manager query key command. For complete command syntax, see the man page. The key ID displayed in the output is an identifier used to refer to the authentication key. It is not the actual authentication key or the data encryption key.

+

The following example verifies that authentication keys have been created for cluster1:

+

```
cluster1::> security key-manager key query
    Vserver: cluster1
    Key Manager: external
        Node: node1

    Key Tag                                Key Type   Restored
    -----  -----  -----
node1                                     NSE-AK     yes
    Key ID:
0000000000000000200000000001000c11b3863f78c2273343d7ec5a67762e0000000
000000000
node1                                     NSE-AK     yes
    Key ID:
0000000000000000200000000001006f4e2513353a674305872a4c9f3bf7970000000
000000000

    Vserver: cluster1
    Key Manager: external
        Node: node2

    Key Tag                                Key Type   Restored
    -----  -----  -----
node2                                     NSE-AK     yes
    Key ID:
0000000000000000200000000001000c11b3863f78c2273343d7ec5a67762e0000000
000000000
node2                                     NSE-AK     yes
    Key ID:
0000000000000000200000000001006f4e2513353a674305872a4c9f3bf7970000000
000000000
```

= Create authentication keys in ONTAP 9.5 and earlier

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./nas-audit../media/

You can use the `security key-manager create-key` command to create the authentication keys for a node and store them on the configured KMIP servers.

What you'll need

You must be a cluster administrator to perform this task.

About this task

If your security setup requires you to use different keys for data authentication and FIPS 140-2 authentication, you should create a separate key for each. If that is not the case, you can use the same authentication key for FIPS compliance that you use for data access.

ONTAP creates authentication keys for all nodes in the cluster.

- This command is not supported when onboard key management is enabled.
- You receive a warning if the configured key management servers are already storing more than 128 authentication keys.

You can use the key management server software to delete any unused keys, then run the command again.

Steps

1. Create the authentication keys for cluster nodes:

```
security key-manager create-key
```

For complete command syntax, see the man page for the command.

The key ID displayed in the output is an identifier used to refer to the authentication key. It is not the actual authentication key or the data encryption key.

+

The following example creates the authentication keys for `cluster1`:

+

```
cluster1::> security key-manager create-key
  (security key-manager create-key)
Verifying requirements...

Node: cluster1-01
Creating authentication key...
Authentication key creation successful.
Key ID:
F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C

Node: cluster1-01
Key manager restore operation initialized.
Successfully restored key information.

Node: cluster1-02
Key manager restore operation initialized.
Successfully restored key information.
```

1. Verify that the authentication keys have been created:

```
security key-manager query
```

For complete command syntax, see the man page.

The following example verifies that authentication keys have been created for `cluster1`:

```

cluster1::> security key-manager query

(security key-manager query)

      Node: cluster1-01
      Key Manager: 20.1.1.1
      Server Status: available

      Key Tag          Key Type  Restored
      -----          -----  -----
cluster1-01      NSE-AK    yes
      Key ID:
F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C

      Node: cluster1-02
      Key Manager: 20.1.1.1
      Server Status: available

      Key Tag          Key Type  Restored
      -----          -----  -----
cluster1-02      NSE-AK    yes
      Key ID:
F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C

```

= Assign a data authentication key to a FIPS drive or SED (external key management)

You can use the `storage encryption disk modify` command to assign a data authentication key to a FIPS drive or SED. Cluster nodes use this key to lock or unlock encrypted data on the drive.

About this task

A self-encrypting drive is protected from unauthorized access only if its authentication key ID is set to a non-default value. The manufacturer secure ID (MSID), which has key ID 0x0, is the standard default value for SAS drives. For NVMe drives, the standard default value is a null key, represented as a blank key ID. When you assign the key ID to a self-encrypting drive, the system changes its authentication key ID to a non-default value.

This procedure is not disruptive.

Before you begin

You must be a cluster administrator to perform this task.

Steps

1. Assign a data authentication key to a FIPS drive or SED:

```
storage encryption disk modify -disk disk_ID -data-key-id key_ID
```

For complete command syntax, see the man page for the command.

You can use the `security key-manager query -key-type NSE-AK` command to view key IDs.

+

```
cluster1::> storage encryption disk modify -disk 0.10.* -data-key-id F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C
```

Info: Starting modify on 14 disks.

View the status of the operation by using the storage encryption disk show-status command.

1. Verify that the authentication keys have been assigned:

```
storage encryption disk show
```

For complete command syntax, see the man page.

```
cluster1::> storage encryption disk show
Disk      Mode Data Key ID
-----  -----
-----
0.0.0    data
F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C
0.0.1    data
F1CB30AFF1CB30B0010100000000000A68B167F92DD54196297159B5968923C
[...]
```

= Configure onboard key management

= Enable onboard key management in ONTAP 9.6 and later

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use the Onboard Key Manager to authenticate cluster nodes to a FIPS drive or SED. The Onboard Key Manager is a built-in tool that serves authentication keys to nodes from the same storage system as your data. The Onboard Key Manager is FIPS-140-2 level 1 compliant.

You can use the Onboard Key Manager to secure the keys that the cluster uses to access encrypted data. You must enable Onboard Key Manager on each cluster that accesses an encrypted volume or a self-encrypting disk.

What you'll need

- If you are using NSE with an external key management (KMIP) server, you must have deleted the external key manager database.

[Transitioning to onboard key management from external key management](#)

- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before the Onboard key manager is configured.

About this task

You must run the `security key-manager onboard enable` command each time you add a node to the cluster. In MetroCluster configurations, you must run `security key-manager onboard enable` on the local cluster first, then run `security key-manager onboard sync` on the remote cluster, using the same passphrase on each.

By default, you are not required to enter the key manager passphrase when a node is rebooted. Except in MetroCluster, you can use the `cc-mode-enabled=yes` option to require that users enter the passphrase after a reboot.

When the Onboard Key Manager is enabled in Common Criteria mode (`cc-mode-enabled=yes`), system behavior is changed in the following ways:

- The system monitors for consecutive failed cluster passphrase attempts when operating in Common Criteria mode.

If NetApp Storage Encryption (NSE) is enabled and you fail to enter the correct cluster passphrase at boot, the system cannot authenticate to its drives and automatically reboots. To correct this, you must enter the correct cluster passphrase at the boot prompt. Once booted, the system allows up to 5 consecutive attempts to correctly enter the cluster passphrase in a 24-hour period for any command that requires the cluster passphrase as a parameter. If the limit is reached (for example, you have failed to correctly enter the cluster passphrase 5 times in a row) then you must either wait for the 24-hour timeout period to elapse, or you must reboot the node, in order to reset the limit.

- System image updates use the NetApp RSA-3072 code signing certificate together with SHA-384 code signed digests to check the image integrity instead of the usual NetApp RSA-2048 code signing certificate and SHA-256 code signed digests.

The upgrade command verifies that the image contents have not been altered or corrupted by checking various digital signatures. The image update process proceeds to the next step if validation succeeds; otherwise, the image update fails. See the “cluster image” man page for information concerning system updates.

The Onboard Key Manager stores keys in volatile memory. Volatile memory contents are cleared when the system is rebooted or halted. Under normal operating conditions, volatile memory contents will be cleared within 30s when a system is halted.

Steps

1. Start the key manager setup command:

```
security key-manager onboard enable -cc-mode-enabled yes|no
```

Set `cc-mode-enabled=yes` to require that users enter the key manager passphrase after a reboot. The `-cc-mode-enabled` option is not supported in MetroCluster configurations. The `security key-manager onboard enable` command replaces the `security key-manager setup` command.

+

The following example starts the key manager setup command on cluster1 without requiring that the passphrase be entered after every reboot:

+

```
cluster1::> security key-manager onboard enable
```

```
Enter the cluster-wide passphrase for onboard key management in Vserver  
"cluster1)::      <32..256 ASCII characters long text>
```

```
Reenter the cluster-wide passphrase:      <32..256 ASCII characters long  
text>
```

1. At the passphrase prompt, enter a passphrase between 32 and 256 characters, or for “cc-mode”, a passphrase between 64 and 256 characters.

If the specified “cc-mode” passphrase is less than 64 characters, there is a five-second delay before the key manager setup operation displays the passphrase prompt again.

1. At the passphrase confirmation prompt, reenter the passphrase.
2. Verify that the authentication keys have been created:

```
security key-manager key query -node node
```

The `security key-manager key query` command replaces the `security key-manager query key` command. For complete command syntax, see the man page.

+

The following example verifies that authentication keys have been created for cluster1:

+

```
cluster1::> security key-manager key query
    Vserver: cluster1
    Key Manager: onboard
        Node: node1

    Key Tag                                Key Type   Restored
    -----  -----  -----
node1                                     NSE-AK     yes
    Key ID:
0000000000000000200000000001000c11b3863f78c2273343d7ec5a67762e0000000
000000000
node1                                     NSE-AK     yes
    Key ID:
0000000000000000200000000001006f4e2513353a674305872a4c9f3bf7970000000
000000000

    Vserver: cluster1
    Key Manager: onboard
        Node: node2

    Key Tag                                Key Type   Restored
    -----  -----  -----
node1                                     NSE-AK     yes
    Key ID:
0000000000000000200000000001000c11b3863f78c2273343d7ec5a67762e0000000
000000000
node2                                     NSE-AK     yes
    Key ID:
0000000000000000200000000001006f4e2513353a674305872a4c9f3bf7970000000
000000000
```

After you finish

Copy the passphrase to a secure location outside the storage system for future use.

All key management information is automatically backed up to the replicated database (RDB) for the cluster. You should also back up the information manually for use in case of a disaster.

= Enable onboard key management in ONTAP 9.5 and earlier

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..../media/

You can use the Onboard Key Manager to authenticate cluster nodes to a FIPS drive or SED. The Onboard Key Manager is a built-in tool that serves authentication keys to nodes from the same storage system as your data. The Onboard Key Manager is FIPS-140-2 level 1 compliant.

You can use the Onboard Key Manager to secure the keys that the cluster uses to access encrypted data. You must enable Onboard Key Manager on each cluster that accesses an encrypted volume or a self-encrypting disk.

What you'll need

- If you are using NSE with an external key management (KMIP) server, you must have deleted the external key manager database.

[Transitioning to onboard key management from external key management](#)

- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before the Onboard Key Manager is configured.

About this task

You must run the `security key-manager setup` command each time you add a node to the cluster.

If you have a MetroCluster configuration, review these guidelines:

- In ONTAP 9.5, you must run `security key-manager setup` on the local cluster and `security key-manager setup -sync-metrocluster-config yes` on the remote cluster, using the same passphrase on each.
- Prior to ONTAP 9.5, you must run `security key-manager setup` on the local cluster, wait approximately 20 seconds, and then run `security key-manager setup` on the remote cluster, using the same passphrase on each.

By default, you are not required to enter the key manager passphrase when a node is rebooted. Beginning with ONTAP 9.4, you can use the `-enable-cc-mode yes` option to require that users enter the passphrase after a reboot.

For NVE, if you set `-enable-cc-mode yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted. For `volume create`, you need not specify `-encrypt true`. For `volume move start`, you need not specify `-encrypt-destination true`.

After a failed passphrase attempt, you must reboot the node again.

Steps

1. Start the key manager setup:

```
security key-manager setup -enable-cc-mode yes|no
```

Beginning with ONTAP 9.4, you can use the `-enable-cc-mode yes` option to require that users enter the key manager passphrase after a reboot. For NVE, if you set `-enable-cc-mode yes`, volumes you create

with the volume create and volume move start commands are automatically encrypted.

+

The following example starts setting up the key manager on cluster1 without requiring that the passphrase be entered after every reboot:

+

```
cluster1::> security key-manager setup
```

```
Welcome to the key manager setup wizard, which will lead you through  
the steps to add boot information.
```

```
...
```

```
Would you like to use onboard key-management? {yes, no} [yes]:
```

```
Enter the cluster-wide passphrase: <32..256 ASCII characters long  
text>
```

```
Reenter the cluster-wide passphrase: <32..256 ASCII characters long  
text>
```

1. Enter yes at the prompt to configure onboard key management.
2. At the passphrase prompt, enter a passphrase between 32 and 256 characters, or for “cc-mode”, a passphrase between 64 and 256 characters.

If the specified “cc-mode” passphrase is less than 64 characters, there is a five-second delay before the key manager setup operation displays the passphrase prompt again.

1. At the passphrase confirmation prompt, reenter the passphrase.

2. Verify that keys are configured for all nodes:

```
security key-manager key show
```

For the complete command syntax, see the man page.

```
cluster1::> security key-manager key show

Node: node1
Key Store: onboard

```

After you finish

All key management information is automatically backed up to the replicated database (RDB) for the cluster.

Whenever you configure the Onboard Key Manager passphrase, you should also back up the information manually to a secure location outside the storage system for use in case of a disaster. See [Back up onboard key management information manually](#).

= Assign a data authentication key to a FIPS drive or SED (onboard key management)

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use the `storage encryption disk modify` command to assign a data authentication key to a FIPS drive or SED. Cluster nodes use this key to access data

on the drive.

What you'll need

You must be a cluster administrator to perform this task.

About this task

A self-encrypting drive is protected from unauthorized access only if its authentication key ID is set to a non-default value. The manufacturer secure ID (MSID), which has key ID 0x0, is the standard default value for SAS drives. For NVMe drives, the standard default value is a null key, represented as a blank key ID. When you assign the key ID to a self-encrypting drive, the system changes its authentication key ID to a non-default value.

Steps

1. Assign a data authentication key to a FIPS drive or SED:

```
storage encryption disk modify -disk disk_ID -data-key-id key_ID
```

For complete command syntax, see the man page for the command.

You can use the security key-manager key query -key-type NSE-AK command to view key IDs.

+

```
cluster1::> storage encryption disk modify -disk 0.10.* -data-key-id  
000000000000000020000000000010019215b9738bc7b43d4698c80246db1f4
```

Info: Starting modify on 14 disks.

View the status of the operation by using the
storage encryption disk show-status command.

1. Verify that the authentication keys have been assigned:

```
storage encryption disk show
```

For complete command syntax, see the man page.

```
cluster1::> storage encryption disk show

000000000000000020000000000010059851742AF2703FC91369B7DB47C4722  
[...]
```

= Assign a FIPS 140-2 authentication key to a FIPS drive

You can use the `storage encryption disk modify` command with the `-fips-key-id` option to assign a FIPS 140-2 authentication key to a FIPS drive. Cluster nodes use this key for drive operations other than data access, such as preventing denial-of-service attacks on the drive.

About this task

Your security setup may require you to use different keys for data authentication and FIPS 140-2 authentication. If that is not the case, you can use the same authentication key for FIPS compliance that you use for data access.

This procedure is not disruptive.

Before you begin

The drive firmware must support FIPS 140-2 compliance. The [NetApp Interoperability Matrix Tool](#) contains information about supported drive firmware versions.

Steps

1. You must first ensure you have assigned a data authentication key. This can be done with using an [external key manager](#) or an [onboard key manager](#). Verify the key is assigned with the command

```
storage encryption disk show.
```

2. Assign a FIPS 140-2 authentication key to SEDs:

```
storage encryption disk modify -disk disk_id -fips-key-id  
fips_authentication_key_id
```

You can use the security key-manager query command to view key IDs.

```
cluster1::> storage encryption disk modify -disk 2.10.* -fips-key-id  
6A1E21D8000000000100000000000005A1FB4EE8F62FD6D8AE6754C9019F35A
```

Info: Starting modify on 14 disks.

View the status of the operation by using the storage encryption disk show-status command.

3. Verify that the authentication key has been assigned:

```
storage encryption disk show -fips
```

For complete command syntax, see the man page.

```
cluster1::> storage encryption disk show -fips  
Disk      Mode FIPS-Compliance Key ID  
-----  
-----  
2.10.0    full  
6A1E21D8000000000100000000000005A1FB4EE8F62FD6D8AE6754C9019F35A  
2.10.1    full  
6A1E21D8000000000100000000000005A1FB4EE8F62FD6D8AE6754C9019F35A  
[...]
```

= Enable cluster-wide FIPS-compliant mode for KMIP server connections

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You can use the security config modify command with the -is-fips-enabled option to enable cluster-wide FIPS-compliant mode for data in flight. Doing so forces the cluster to use OpenSSL in FIPS mode when connecting to KMIP servers.

Before you begin

- The storage controller must be configured in FIPS-compliant mode.
- All KMIP servers must support TLSv1.2. The system requires TLSv1.2 to complete the connection to the KMIP server when cluster-wide FIPS-compliant mode is enabled.

About this task

When you enable cluster-wide FIPS-compliant mode, the cluster will automatically use only TLS1.2 and FIPS-validated cipher suites. Cluster-wide FIPS-compliant mode is disabled by default.

You must reboot cluster nodes manually after modifying the cluster-wide security configuration.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Verify that TLSv1.2 is supported:

```
security config show -supported-protocols
```

For complete command syntax, see the man page.

```
cluster1::> security config show
      Cluster
Cluster Security
Interface FIPS Mode  Supported Protocols      Supported Ciphers
Config Ready
-----
-----
SSL        false       TLSv1.2, TLSv1.1, TLSv1 ALL:!LOW:           yes
                           !aNULL:!EXP:
                           !eNULL
```

3. Enable cluster-wide FIPS-compliant mode:

```
security config modify -is-fips-enabled true -interface SSL
```

For complete command syntax, see the man page.

4. Reboot cluster nodes manually.

5. Verify that cluster-wide FIPS-compliant mode is enabled:

```
security config show
```

```

cluster1::> security config show
      Cluster
Cluster Security
Interface FIPS Mode   Supported Protocols      Supported Ciphers
Config Ready
-----
-----
SSL       true        TLSv1.2, TLSv1.1      ALL:!LOW:
                                                !aNULL:!EXP:
                                                !eNULL:!RC4

```

= Manage NetApp encryption

= Unencrypt volume data

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use the `volume move start` command to move and unencrypt volume data.

What you'll need

You must be a cluster administrator to perform this task, or an SVM administrator to whom the cluster administrator has delegated authority.

[Delegating authority to run the volume move command](#)

Steps

1. Move an existing encrypted volume and unencrypt the data on the volume:

```

volume move start -vserver SVM_name -volume volume_name -destination
-aggregate aggregate_name -encrypt-destination false

```

For complete command syntax, see the man page for the command.

The following command moves an existing volume named `vol1` to the destination aggregate `aggr3` and unencrypts the data on the volume:

```

cluster1::> volume move start -vserver vs1 -volume vol1 -destination
-aggregate aggr3 -encrypt-destination false

```

The system deletes the encryption key for the volume. The data on the volume is unencrypted.

2. Verify that the volume is disabled for encryption:

```

volume show -encryption

```

For complete command syntax, see the man page for the command.

The following command displays whether volumes on cluster1 are encrypted:

```
cluster1::> volume show -encryption
```

Vserver	Volume	Aggregate	State	Encryption State
vs1	vol1	aggr1	online	none

= Move an encrypted volume

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use the `volume move start` command to move an encrypted volume. The moved volume can reside on the same aggregate or a different aggregate.

What you'll need

You must be a cluster administrator to perform this task, or an SVM administrator to whom the cluster administrator has delegated authority.

[Delegating authority to run the volume move command](#)

About this task

The move will fail if the destination node or destination volume does not support volume encryption.

The `-encrypt-destination` option for `volume move start` defaults to true for encrypted volumes. Requiring you to specify explicitly that you do not want the destination volume to be encrypted ensures that you do not inadvertently unencrypt the data on the volume.

Steps

1. Move an existing encrypted volume and leave the data on the volume encrypted:

```
volume move start -vserver SVM_name -volume volume_name -destination  
-aggregate aggregate_name
```

For complete command syntax, see the man page for the command.

The following command moves an existing volume named `vol1` to the destination aggregate `aggr3` and leaves the data on the volume encrypted:

```
cluster1::> volume move start -vserver vs1 -volume vol1 -destination  
-aggregate aggr3
```

2. Verify that the volume is enabled for encryption:

```
volume show -is-encrypted true
```

For complete command syntax, see the man page for the command.

The following command displays the encrypted volumes on cluster1:

```
cluster1::> volume show -is-encrypted true

Vserver    Volume   Aggregate   State   Type   Size   Available   Used
-----  -----  -----  -----  -----  -----  -----  -----
vs1        vol1     aggr3      online   RW    200GB    160.0GB   20%
```

= Delegate authority to run the volume move command

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use the `volume move` command to encrypt an existing volume, move an encrypted volume, or unencrypt a volume. Cluster administrators can run `volume move` command themselves, or they can delegate the authority to run the command to SVM administrators.

About this task

By default, SVM administrators are assigned the `vsadmin` role, which does not include the authority to move volumes. You must assign the `vsadmin-volume` role to SVM administrators to enable them to run the `volume move` command.

Step

1. Delegate authority to run the `volume move` command:

```
security login modify -vserver SVM_name -user-or-group-name
user_or_group_name -application application -authmethod
authentication_method -role vsadmin-volume
```

For complete command syntax, see the man page for the command.

The following command grants the SVM administrator authority to run the `volume move` command.

```
cluster1::>security login modify -vserver engData -user-or-group
-name SVM-admin -application ssh -authmethod domain -role vsadmin-
volume
```

= Change the encryption key for a volume with the `volume encryption rekey start` command

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

It is a security best practice to change the encryption key for a volume periodically. Beginning with ONTAP 9.3, you can use the `volume encryption rekey start` command to change the encryption key.

About this task

Once you start a rekey operation, it must complete. There is no returning to the old key. If you encounter a performance issue during the operation, you can run the `volume encryption rekey pause` command to pause the operation, and the `volume encryption rekey resume` command to resume the operation.

Until the rekey operation finishes, the volume will have two keys. New writes and their corresponding reads will use the new key. Otherwise, reads will use the old key.

You cannot use `volume encryption rekey start` to rekey a SnapLock volume.

Steps

1. Change an encryption key:

```
volume encryption rekey start -vserver SVM_name -volume volume_name
```

The following command changes the encryption key for vol1 on SVMvs1:

```
cluster1::> volume encryption rekey start -vserver vs1 -volume vol1
```

2. Verify the status of the rekey operation:

```
volume encryption rekey show
```

For complete command syntax, see the man page for the command.

The following command displays the status of the rekey operation:

```
cluster1::> volume encryption rekey show
```

Vserver	Volume	Start Time	Status
vs1	vol1	9/18/2017 17:51:41	Phase 2 of 2 is in progress.

3. When the rekey operation is complete, verify that the volume is enabled for encryption:

```
volume show -is-encrypted true
```

For complete command syntax, see the man page for the command.

The following command displays the encrypted volumes on cluster1:

```
cluster1::> volume show -is-encrypted true
```

Vserver	Volume	Aggregate	State	Type	Size	Available	Used
vs1	vol1	aggr2	online	RW	200GB	160.0GB	20%

= Change the encryption key for a volume with the volume move start command
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

It is a security best practice to change the encryption key for a volume periodically. You can use the volume move start command to change the encryption key. You must use volume move start in ONTAP 9.2 and earlier. The moved volume can

reside on the same aggregate or a different aggregate.

What you'll need

You must be a cluster administrator to perform this task, or an SVM administrator to whom the cluster administrator has delegated authority.

Delegating authority to run the volume move command

About this task

You cannot use `volume move start` to rekey a SnapLock or FlexGroup volume.

Steps

1. Move an existing volume and change the encryption key:

```
volume move start -vserver SVM_name -volume volume_name -destination  
-aggregate aggregate_name -generate-destination-key true
```

For complete command syntax, see the man page for the command.

The following command moves an existing volume named `vol1` to the destination aggregate `aggr2` and changes the encryption key:

```
cluster1::> volume move start -vserver vs1 -volume vol1 -destination  
-aggregate aggr2 -generate-destination-key true
```

A new encryption key is created for the volume. The data on the volume remains encrypted.

2. Verify that the volume is enabled for encryption:

```
volume show -is-encrypted true
```

For complete command syntax, see the man page for the command.

The following command displays the encrypted volumes on `cluster1`:

```
cluster1::> volume show -is-encrypted true
```

Vserver	Volume	Aggregate	State	Type	Size	Available	Used
vs1	vol1	aggr2	online	RW	200GB	160.0GB	20%

= Rotate authentication keys for NetApp Storage Encryption

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can rotate authentication keys when using NetApp Storage Encryption (NSE).

About this task

Rotating authentication keys in an NSE environment is supported if you are using External Key Manager (KMIP).

Rotating authentication keys in an NSE environment is not supported for Onboard Key Manager (OKM).

Steps

1. Use the `security key-manager create-key` command to generate new authentication keys.

You need to generate new authentication keys before you can change the authentication keys.

2. Use the `storage encryption disk modify -disk * -data-key-id` command to change the authentication keys.

= Delete an encrypted volume

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You can use the `volume delete` command to delete an encrypted volume.

What you'll need

- You must be a cluster administrator to perform this task, or an SVM administrator to whom the cluster administrator has delegated authority.

[Delegating authority to run the volume move command](#)

- The volume must be offline.

Step

1. Delete an encrypted volume:

```
volume delete -vserver SVM_name -volume volume_name
```

For complete command syntax, see the man page for the command.

The following command deletes an encrypted volume named `vol1`:

```
cluster1::> volume delete -vserver vs1 -volume vol1
```

Enter `yes` when you are prompted to confirm deletion.

The system deletes the encryption key for the volume after 24 hours.

Use `volume delete` with the `-force true` option to delete a volume and destroy the corresponding encryption key immediately. This command requires advanced privileges. For more information, see the man page.

After you finish

You can use the `volume recovery-queue` command to recover a deleted volume during the retention period after issuing the `volume delete` command:

```
volume recovery-queue SVM_name -volume volume_name
```

[How to use the Volume Recovery feature](#)

= Securely purge data on an encrypted volume

= Securely purge data on an encrypted volume overview

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

Beginning with ONTAP 9.4, you can use secure purge to non-disruptively scrub data on NVE-enabled volumes. Scrubbing data on an encrypted volume ensures that it cannot be recovered from the physical media, for example, in cases of “spillage,” where data traces may have been left behind when blocks were overwritten, or for securely deleting a vacating tenant’s data.

Secure purge works only for previously deleted files on NVE-enabled volumes. You cannot scrub an unencrypted volume. You must use KMIP servers to serve keys, not the onboard key manager.

== Considerations for using secure purge

- * Volumes created in an aggregate enabled for NetApp Aggregate Encryption (NAE) do not support secure purge.
- * Secure purge works only for previously deleted files on NVE-enabled volumes.
- * You cannot scrub an unencrypted volume.
- * You must use KMIP servers to serve keys, not the onboard key manager.

Secure purge functions differently depending upon your version of ONTAP.

- Secure purge is supported by MetroCluster and FlexGroup.
- If the volume being purged is the source of a SnapMirror relationship, you do not have to break the SnapMirror relationship to perform a secure purge.
- The re-encryption method is different for volumes using SnapMirror data protection versus volumes not using SnapMirror data protection (DP) or those using SnapMirror extended data protection..
 - By default, volumes using SnapMirror data protection (DP) mode re-encrypt data using the volume move re-encryption method.
 - By default, volumes not using SnapMirror data protection or volumes using SnapMirror extended data protection (XDP) mode use the in-place re-encryption method.
 - These defaults can be changed using the `secure purge re-encryption-method [volume-move|in-place-rekey]` command.
- By default, all Snapshot copies in FlexVol volumes are automatically deleted during the secure purge operation. By default, Snapshots in FlexGroup volumes and volumes using SnapMirror data protection are not automatically deleted during the secure purge operation. These defaults can be changed using the `secure purge delete-all-snapshots [true|false]` command.
- Secure purge does not support the following:
 - FlexClone
 - SnapVault
 - FabricPool
- If the volume being purged is the source of a SnapMirror relationship, you must break the SnapMirror relationship before you can purge the volume.

If there are busy Snapshot copies in the volume, you must release the Snapshot copies before you can purge the volume. For example, you may need to split a FlexClone volume from its parent.

- Successfully invoking the secure-purge feature triggers a volume move that re-encrypts the remaining, unpurged data with a new key.

The moved volume remains on the current aggregate. The old key is automatically destroyed, ensuring that purged data cannot be recovered from the storage media.

= Securely purge data on an encrypted volume without a SnapMirror relationship

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

Beginning with ONTAP 9.4, you can use secure-purge to non-disruptively “scrub” data on NVE-enabled volumes.

What you'll need

- You must be a cluster administrator to perform this task.
- Advanced privileges are required for this task.

About this task

Secure-purge may take from several minutes to many hours to complete, depending on the amount of data in the deleted files. You can use the `volume encryption secure-purge show` command to view the status of the operation. You can use the `volume encryption secure-purge abort` command to terminate the operation.

In order to do a secure purge on a SAN host, you must delete the entire LUN containing the files you want to purge, or you must be able to punch holes in the LUN for the blocks that belong to the files you want purge. If you cannot delete the LUN or your host operating system does not support punching holes in the LUN, you cannot perform a secure purge.

Steps

1. Delete the files or the LUN you want to securely purge.
 - On a NAS client, delete the files you want to securely purge.
 - On a SAN host, delete the LUN you want to securely purge or punch holes in the LUN for the blocks that belong to the files you want to purge.
2. On the storage system, change to advanced privilege level:

```
set -privilege advanced
```

3. If the files you want to securely purge are in snapshots, delete the snapshots:

```
snapshot delete -vserver SVM_name -volume vol_name -snapshot
```

4. Securely purge the deleted files:

```
volume encryption secure-purge start -vserver SVM_name -volume volume_name
```

The following command securely purges the deleted files on vol1 on SVMvs1:

```
cluster1::> volume encryption secure-purge start -vserver vs1  
-volume vol1
```

5. Verify the status of the secure-purge operation:

```
volume encryption secure-purge show
```

= Securely purge data on an encrypted volume with an Asynchronous SnapMirror relationship

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

Beginning with ONTAP 9.8, you can use a secure purge to non-disruptively “scrub” data on NVE-enabled volumes with an Asynchronous SnapMirror relationship.

What you'll need

- You must be a cluster administrator to perform this task.
- Advanced privileges are required for this task.

About this task

Secure-purge may take from several minutes to many hours to complete, depending on the amount of data in the deleted files. You can use the `volume encryption secure-purge show` command to view the status of the operation. You can use the `volume encryption secure-purge abort` command to terminate the operation.

In order to do a secure purge on a SAN host, you must delete the entire LUN containing the files you want to purge, or you must be able to punch holes in the LUN for the blocks that belong to the files you want to purge. If you cannot delete the LUN or your host operating system does not support punching holes in the LUN, you

cannot perform a secure purge.

Steps

1. On the storage system, change to advanced privilege level:

```
set -privilege advanced
```

2. Delete the files or the LUN you want to securely purge.

- On a NAS client, delete the files you want to securely purge.
- On a SAN host, delete the LUN you want to securely purge or punch holes in the LUN for the blocks that belong to the files you want to purge.

3. Prepare the destination volume in the Asynchronous relationship to be securely purged:

```
volume encryption secure-purge start -vserver SVM_name -volume volume_name  
-prepare true
```

Repeat this step on each volume in your Asynchronous SnapMirror relationship.

4. If the files you want to securely purge are in Snapshot copies, delete the Snapshot copies:

```
snapshot delete -vserver SVM_name -volume vol_name -snapshot
```

5. If the files you want to securely purge are in the base Snapshot copies, do the following:

- a. Create a Snapshot copy on the destination volume in the Asynchronous SnapMirror relationship:

```
volume snapshot create -snapshot snapshot_name -vserver SVM_name -volume  
vol_name
```

- b. Update SnapMirror to move the base Snapshot copy forward:

```
snapmirror update -source-snapshot snapshot_name -destination-path  
destination_path
```

Repeat this step for each volume in the Asynchronous SnapMirror relationship.

- c. Repeat steps (a) and (b) equal to the number of base Snapshot copies plus one.

For example, if you have two base Snapshot copies, you should repeat steps (a) and (b) three times.

- d. Verify that the base Snapshot copy is present:

```
snapshot show -vserver SVM_name -volume vol_name`
```

- e. Delete the base Snapshot copy:

```
snapshot delete -vserver SVM_name -volume vol_name -snapshot snapshot
```

6. Securely purge the deleted files:

```
volume encryption secure-purge start -vserver SVM_name -volume volume_name
```

Repeat this step on each volume in the Asynchronous SnapMirror relationship.

The following command securely purges the deleted files on “vol1” on SVM “vs1”:

```
cluster1::> volume encryption secure-purge start -vserver vs1  
-volume vol1
```

7. Verify the status of the secure purge operation:

```
volume encryption secure-purge show
```

= Scrub data on an encrypted volume with a Synchronous SnapMirror relationship
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

Beginning with ONTAP 9.8, you can use a secure purge to non-disruptively “scrub” data on NVE-enabled volumes with a Synchronous SnapMirror relationship.

What you'll need

- You must be a cluster administrator to perform this task.
- Advanced privileges are required for this task.

About this task

A secure purge might take from several minutes to many hours to complete, depending on the amount of data in the deleted files. You can use the `volume encryption secure-purge show` command to view the status of the operation. You can use the `volume encryption secure-purge abort` command to terminate the operation.

In order to do a secure purge on a SAN host, you must delete the entire LUN containing the files you want to purge, or you must be able to punch holes in the LUN for the blocks that belong to the files you want purge. If you cannot delete the LUN or your host operating system does not support punching holes in the LUN, you cannot perform a secure purge.

Steps

1. On the storage system, change to advanced privilege level:

```
set -privilege advanced
```

2. Delete the files or the LUN you want to securely purge.

- On a NAS client, delete the files you want to securely purge.
- On a SAN host, delete the LUN you want to securely purge or punch holes in the LUN for the blocks that belong to the files you want to purge.

3. Prepare the destination volume in the Asynchronous relationship to be securely purged:

```
volume encryption secure-purge start -vserver SVM_name -volume volume_name  
-prepare true
```

Repeat this step for the other volume in your Synchronous SnapMirror relationship.

4. If the files you want to securely purge are in Snapshot copies, delete the Snapshot copies:

```
snapshot delete -vserver SVM_name -volume vol_A -snapshot snapshot
```

5. If the secure purge file is in the base or common Snapshot copies, update the SnapMirror to move the common Snapshot copy forward:

```
snapmirror update -source-snapshot snapshot_name -destination-path  
destination_path
```

There are two common Snapshot copies, so this command must be issued twice.

6. If the secure purge file is in the application-consistent Snapshot copy, delete the Snapshot copy on both volumes in the Synchronous SnapMirror relationship:

```
snapshot delete -vserver SVM_name -volume vol_name -snapshot snapshot
```

Perform this step on both volumes.

7. Securely purge the deleted files:

```
volume encryption secure-purge start -vserver SVM_name -volume volume_name
```

Repeat this step on each volume in the synchronous SnapMirror relationship.

The following command securely purges the deleted files on “vol1” on SMV “vs1”.

```
cluster1::> volume encryption secure-purge start -vserver vs1  
-volume vol1
```

8. Verify the status of the secure purge operation:

```
volume encryption secure-purge show
```

= Change the onboard key management passphrase

It is a security best practice to change the onboard key management passphrase periodically. You should copy the new onboard key management passphrase to a secure location outside the storage system for future use.

What you'll need

- You must be a cluster or SVM administrator to perform this task.
- Advanced privileges are required for this task.

Steps

1. Change to advanced privilege level:

```
set -privilege advanced
```

2. Change the onboard key management passphrase:

For this ONTAP version...	Use this command...
ONTAP 9.6 and later	security key-manager onboard update-passphrase
ONTAP 9.5 and earlier	security key-manager update-passphrase

For complete command syntax, see the man pages.

The following ONTAP 9.6 command lets you change the onboard key management passphrase for cluster1:

```
cluster1::> security key-manager onboard update-passphrase
Warning: This command will reconfigure the cluster passphrase for
onboard key management for Vserver "cluster1".
Do you want to continue? {y|n}: y
Enter current passphrase:
Enter new passphrase:
```

3. Enter **y** at the prompt to change the onboard key management passphrase.
4. Enter the current passphrase at the current passphrase prompt.
5. At the new passphrase prompt, enter a passphrase between 32 and 256 characters, or for “cc-mode”, a passphrase between 64 and 256 characters.

If the specified “cc-mode” passphrase is less than 64 characters, there is a five-second delay before the key manager setup operation displays the passphrase prompt again.

6. At the passphrase confirmation prompt, reenter the passphrase.

After you finish

In a MetroCluster environment, you must update the passphrase on the partner cluster:

- In ONTAP 9.5 and earlier, you must run `security key-manager update-passphrase` with the same passphrase on the partner cluster.
- In ONTAP 9.6 and later, you are prompted to run `security key-manager onboard sync` with the same passphrase on the partner cluster.

You should copy the onboard key management passphrase to a secure location outside the storage system for future use.

You should back up key management information manually whenever you change the onboard key management passphrase.

[Backing up onboard key management information manually](#)

= Back up onboard key management information manually

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You should copy onboard key management information to a secure location outside the storage system whenever you configure the Onboard Key Manager passphrase.

What you'll need

- You must be a cluster administrator to perform this task.
- Advanced privileges are required for this task.

About this task

All key management information is automatically backed up to the replicated database (RDB) for the cluster. You should also back up key management information manually for use in case of a disaster.

Steps

1. Change to advanced privilege level:

```
set -privilege advanced
```

2. Display the key management backup information for the cluster:

For this ONTAP version...	Use this command...
ONTAP 9.6 and later	<code>security key-manager onboard show-backup</code>
ONTAP 9.5 and earlier	<code>security key-manager backup show</code>

For complete command syntax, see the man pages.

+

The following 9.6 command displays the key management backup information for `cluster1`:

+

```
cluster1::> security key-manager onboard show-backup
```

1. Copy the backup information to a secure location outside the storage system for use in case of a disaster.

= Restore onboard key management encryption keys

:icons: font

:relative path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/../encryption-at-rest/..../media/

If need to restore an onboard key management encryption key, you first verify that a key needs to be restored, then you can set up the Onboard Key Manager to restore the key.

Before you begin

- If you are using NSE with an external key management (KMIP) server, you must have deleted the external key manager database.

Transitioning to onboard key management from external key management

- You must be a cluster administrator to perform this task.

== Steps for ONTAP 9.6 and later

1. Verify that the key needs to be restored:

```
security key-manager key query -node node
```

2. If you are running ONTAP 9.8 and later, and your root volume is encrypted, complete [\[root_volume_encrypted\]](#).

If you are running ONTAP 9.6 or 9.7, or if you are running ONTAP 9.8 or later and your root volume is not encrypted, skip this step.

3. Restore the key:

```
security key-manager onboard sync
```

For complete command syntax, see the man pages.

The following ONTAP 9.6 command synchronize the keys in the onboard key hierarchy:

```
cluster1::> security key-manager onboard sync
```

```
Enter the cluster-wide passphrase for onboard key management in  
Vserver "cluster1":<32..256 ASCII characters long text>
```

4. At the passphrase prompt, enter the onboard key management passphrase for the cluster.

== Steps for ONTAP 9.5 and earlier

1. Verify that the key needs to be restored:

```
security key-manager key show
```

2. If you are running ONTAP 9.8 and later, and your root volume is encrypted, complete these steps:

If you are running ONTAP 9.6 or 9.7, or if you are running ONTAP 9.8 or later and your root volume is not encrypted, skip this step.

3. Restore the key:

```
security key-manager setup -node node
```

For complete command syntax, see the man pages.

4. At the passphrase prompt, enter the onboard key management passphrase for the cluster.

== Steps if the root volume is encrypted

If you are running ONTAP 9.8 and later, and your root volume is encrypted, you must set an onboard key management recovery passphrase with the boot menu. This process is also necessary if you do a boot

media replacement.

1. Boot the node to the boot menu and select option (10) Set onboard key management recovery secrets.
2. Enter **y** to use this option.
3. At the prompt, enter the onboard key management passphrase for the cluster.
4. At the prompt, enter the backup key data.

The node returns to the boot menu.

5. From the boot menu, select option (1) Normal Boot.

= Restore external key management encryption keys

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source//encryption-at-rest//media/

You can manually restore external key management encryption keys and “push” them to a different node. You might want to do this if you are restarting a node that was down temporarily when you created the keys for the cluster.

What you'll need

You must be a cluster or SVM administrator to perform this task.

About this task

In ONTAP 9.6 and later, you can use the security key-manager key query -node node_name command to verify if your key needs to be restored.

In ONTAP 9.5 and earlier, you can use the security key-manager key show command to verify if your key needs to be restored.

Steps

1. If you are running ONTAP 9.8 or later and your root volume is encrypted, do the following:

If you are running ONTAP 9.7 or earlier, or if you are running ONTAP 9.8 or later and your root volume is not encrypted, skip this step.

- a. Set the bootargs:

```
setenv kmip.init.ipaddr <ip-address>
setenv kmip.init.netmask <netmask>
setenv kmip.init.gateway <gateway>
setenv kmip.init.interface e0M
boot_ontap
```

- b. Boot the node to the boot menu and select option (11) Configure node for external key management.

- c. Follow prompts to enter management certificate.

After all management certificate information is entered, the system returns to the boot menu.

- d. From the boot menu, select option (1) Normal Boot.

2. Restore the key:

For this ONTAP version...	Use this command...
ONTAP 9.6 and later	<pre>security key-manager external restore -vserver SVM -node node -key-server host_name IP_address:port -key-id key_id -key -tag key_tag</pre>
ONTAP 9.5 and earlier	<pre>security key-manager restore -node node -address IP_address -key-id key_id -key-tag key_tag</pre>

node defaults to all nodes. For complete command syntax, see the man pages. This command is not supported when onboard key management is enabled.

+

The following ONTAP 9.6 command restores external key management authentication keys to all nodes in cluster1:

+

```
cluster1::> security key-manager external restore
```

= Replace SSL certificates

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

All SSL certificates have an expiration date. You must update your certificates before they expire to prevent loss of access to authentication keys.

Before you begin

- You must have obtained the replacement public certificate and private key for the cluster (KMIP client certificate).
- You must have obtained the replacement public certificate for the KMIP server (KMIP server-ca certificate).
- You must be a cluster or SVM administrator to perform this task.
- In a MetroCluster environment, you must replace the KMIP SSL certificate on both clusters.

You can install the replacement client and server certificates on the KMIP server before or after installing the certificates on the cluster.

Steps

1. Install the new KMIP server-ca certificate:

```
security certificate install -type server-ca -vserver <>
```

2. Install the new KMIP client certificate:

```
security certificate install -type client -vserver <>
```

3. Update the key manager configuration to use the newly installed certificates:

```
security key-manager external modify -vserver <> -client-cert <> -server-ca-certs <>
```

If you are running ONTAP 9.6 or later in a MetroCluster environment, and you want to modify the key manager configuration on the admin SVM, you must run the command on both clusters in the configuration.

i Updating the key manager configuration to use the newly installed certificates will return an error if the public/private keys of the new client certificate are different from the keys previously installed. See the Knowledge Base article [The new client certificate public or private keys are different from the existing client certificate](#) for instructions on how to override this error.

= Replace a FIPS drive or SED

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can replace a FIPS drive or SED the same way you replace an ordinary disk. Make sure to assign new data authentication keys to the replacement drive. For a FIPS drive, you may also want to assign a new FIPS 140-2 authentication key.

i If an HA pair is using [encrypting SAS or NVMe drives \(SED, NSE, FIPS\)](#), you must follow the instructions in the topic [Returning a FIPS drive or SED to unprotected mode](#) for all drives within the HA pair prior to initializing the system (boot options 4 or 9). Failure to do this may result in future data loss if the drives are repurposed.

What you'll need

- You must know the key ID for the authentication key used by the drive.
- You must be a cluster administrator to perform this task.

Steps

1. Ensure that the disk has been marked as failed:

```
storage disk show -broken
```

For complete command syntax, see the man page.

```
cluster1::> storage disk show -broken
Original Owner: cluster1-01
Checksum Compatibility: block

Usable Physical
  Disk    Outage Reason HA Shelf Bay Chan   Pool   Type      RPM
Size     Size
-----  -----  -----  -----  -----  -----  -----  -----
-----  -----
  0.0.0  admin   failed  0b      1     0     A  Pool0  FCAL  10000
132.8GB 133.9GB
  0.0.7  admin   removed 0b      2     6     A  Pool1  FCAL  10000
132.8GB 134.2GB
[...]
```

2. Remove the failed disk and replace it with a new FIPS drive or SED, following the instructions in the hardware guide for your disk shelf model.

3. Assign ownership of the newly replaced disk:

```
storage disk assign -disk disk_name -owner node
```

For complete command syntax, see the man page.

```
cluster1::> storage disk assign -disk 2.1.1 -owner cluster1-01
```

4. Confirm that the new disk has been assigned:

```
storage encryption disk show
```

For complete command syntax, see the man page.

```
cluster1::> storage encryption disk show
Disk      Mode Data Key ID
-----  -----
0.0.0    data
F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C
0.0.1    data
F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C
1.10.0   data
F1CB30AFF1CB30B001010000000000CF0EFD81EA9F6324EA97B369351C56AC
1.10.1   data
F1CB30AFF1CB30B001010000000000CF0EFD81EA9F6324EA97B369351C56AC
2.1.1    open 0x0
[...]
```

5. Assign the data authentication keys to the FIPS drive or SED.

[Assigning a data authentication key to a FIPS drive or SED \(external key management\)](#)

6. If necessary, assign a FIPS 140-2 authentication key to the FIPS drive.

[Assigning a FIPS 140-2 authentication key to a FIPS drive](#)

= Make data on a FIPS drive or SED inaccessible

= Make data on a FIPS drive or SED inaccessible overview

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

If you want to make data on a FIPS drive or SED permanently inaccessible, but keep the drive's unused space available for new data, you can sanitize the disk. If you want to make data permanently inaccessible and you do not need to reuse the drive,

you can destroy it.

- Disk sanitization

When you sanitize a self-encrypting drive, the system changes the disk encryption key to a new random value, resets the power-on lock state to false, and sets the key ID to a default value, either the manufacturer secure ID 0x0 (SAS drives) or a null key (NVMe drives). Doing so renders the data on the disk inaccessible and impossible to retrieve. You can reuse sanitized disks as non-zeroed spare disks.

- Disk destroy

When you destroy a FIPS drive or SED, the system sets the disk encryption key to an unknown random value and locks the disk irreversibly. Doing so renders the disk permanently unusable and the data on it permanently inaccessible.

You can sanitize or destroy individual self-encrypting drives, or all the self-encrypting drives for a node.

= Sanitize a FIPS drive or SED

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

If you want to make data on a FIPS drive or SED permanently inaccessible, and use the drive for new data, you can use the `storage encryption disk sanitize` command to sanitize the drive.

What you'll need

You must be a cluster administrator to perform this task.

About this task

When you sanitize a self-encrypting drive, the system changes the disk encryption key to a new random value, resets the power-on lock state to false, and sets the key ID to a default value, either the manufacturer secure ID 0x0 (SAS drives) or a null key (NVMe drives). Doing so renders the data on the disk inaccessible and impossible to retrieve. You can reuse sanitized disks as non-zeroed spare disks.

Steps

1. Migrate any data that needs to be preserved to an aggregate on another disk.
2. Delete the aggregate on the FIPS drive or SED to be sanitized:

```
storage aggregate delete -aggregate aggregate_name
```

For complete command syntax, see the man page.

```
cluster1::> storage aggregate delete -aggregate aggr1
```

3. Identify the disk ID for the FIPS drive or SED to be sanitized:

```
storage encryption disk show -fields data-key-id,fips-key-id,owner
```

For complete command syntax, see the man page.

```
cluster1::> storage encryption disk show
Disk      Mode Data Key ID
----  -----
-----
0.0.0    data
F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C
0.0.1    data
F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C
1.10.2   data
F1CB30AFF1CB30B001010000000000CF0EFD81EA9F6324EA97B369351C56AC
[...]
```

4. If a FIPS drive is running in FIPS-compliance mode, set the FIPS authentication key ID for the node back to the default MSID 0x0:

```
storage encryption disk modify -disk disk_id -fips-key-id 0x0
```

You can use the `security key-manager query` command to view key IDs.

```
cluster1::> storage encryption disk modify -disk 1.10.2 -fips-key-id
0x0
```

Info: Starting modify on 1 disk.

View the status of the operation by using the
`storage encryption disk show-status` command.

5. Sanitize the drive:

```
storage encryption disk sanitize -disk disk_id
```

You can use this command to sanitize hot spare or broken disks only. To sanitize all disks regardless of type, use the `-force-all-state` option. For complete command syntax, see the man page.

You are prompted to enter a confirmation phrase before continuing. Enter the phrase exactly as shown on the screen.

+

```
cluster1::> storage encryption disk sanitize -disk 1.10.2
```

Warning: This operation will cryptographically sanitize 1 spare or broken self-encrypting disk on 1 node.

To continue, enter sanitize disk: sanitize disk

Info: Starting sanitize on 1 disk.

View the status of the operation using the storage encryption disk show-status command.

= Destroy a FIPS drive or SED

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

If you want to make data on a FIPS drive or SED permanently inaccessible and you do not need to reuse the drive, you can use the storage encryption disk destroy command to destroy the disk.

What you'll need

You must be a cluster administrator to perform this task.

About this task

When you destroy a FIPS drive or SED, the system sets the disk encryption key to an unknown random value and locks the drive irreversibly. Doing so renders the disk virtually unusable and the data on it permanently inaccessible. However, you can reset the disk to its factory-configured settings using the physical secure ID (PSID) printed on the disk's label. For more information, see [Returning a FIPS drive or SED to service when authentication keys are lost](#).

You should not destroy a FIPS drive or SED unless you have the Non-Returnable Disk Plus service (NRD Plus). Destroying a disk voids its warranty.

Steps

1. Migrate any data that needs to be preserved to an aggregate on another different disk.
2. Delete the aggregate on the FIPS drive or SED to be destroyed:

```
storage aggregate delete -aggregate aggregate_name
```

For complete command syntax, see the man page.

```
cluster1::> storage aggregate delete -aggregate aggr1
```

3. Identify the disk ID for the FIPS drive or SED to be destroyed:

```
storage encryption disk show
```

For complete command syntax, see the man page.

```
cluster1::> storage encryption disk show
Disk      Mode Data Key ID
-----  -----
-----
0.0.0    data
F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C
0.0.1    data
F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C
1.10.2   data
F1CB30AFF1CB30B001010000000000CF0EFD81EA9F6324EA97B369351C56AC
[...]
```

4. Destroy the disk:

```
storage encryption disk destroy -disk disk_id
```

For complete command syntax, see the man page.

You are prompted to enter a confirmation phrase before continuing. Enter the phrase exactly as shown on the screen.

+

```
cluster1::> storage encryption disk destroy -disk 1.10.2
```

Warning: This operation will cryptographically destroy 1 spare or broken

self-encrypting disks on 1 node.

You cannot reuse destroyed disks unless you revert them to their original state using the PSID value.

To continue, enter

destroy disk

:destroy disk

Info: Starting destroy on 1 disk.

View the status of the operation by using the "storage encryption disk show-status" command.

= Emergency shredding of data on a FIPS drive or SED

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

In case of a security emergency, you can instantly prevent access to a FIPS drive or SED, even if power is not available to the storage system or the KMIP server.

What you'll need

- If you are using a KMIP server that has no available power, the KMIP server must be configured with an easily destroyed authentication item (for example, a smart card or USB drive).
- You must be a cluster administrator to perform this task.

Step

1. Perform emergency shredding of data on a FIPS drive or SED:

If...	Then...
-------	---------

Power is available to the storage system and you have time to take the storage system offline gracefully

a. If the storage system is configured as an HA pair, disable takeover.

b. Take all aggregates offline and delete them.

c. Set the privilege level to advanced:

```
set -privilege advanced
```

d. If the drive is in FIPS-compliance mode, set the FIPS authentication key ID for the node back to the default MSID:

```
storage encryption disk modify -disk * -fips  
-key-id 0x0
```

e. Halt the storage system.

f. Boot into maintenance mode.

g. Sanitize or destroy the disks:

- If you want to make the data on the disks inaccessible and still be able to reuse the disks, sanitize the disks:

```
disk encrypt sanitize -all
```

- If you want to make the data on the disks inaccessible and you do not need to save the disks, destroy the disks:

```
disk encrypt destroy disk_id1 disk_id2 ...
```

The `disk encrypt sanitize` and `disk encrypt destroy` commands are reserved for maintenance mode only. These commands must be run on each HA node, and are not available for broken disks.

- a. Repeat these steps for the partner node.

This leaves the storage system in a permanently disabled state with all data erased. To use the system again, you must reconfigure it.

2+a| Power is available to the storage system and you must shred the data immediately

a| .. If you want to make the data on the disks inaccessible and still be able to reuse the disks, sanitize the disks:

.. If the storage system is configured as an HA pair, disable takeover.

.. Set the privilege level to advanced:

+

```
set -privilege advanced
```

.. If the drive is in FIPS-compliance mode, set the FIPS authentication key ID for the node back to the default MSID:

+

```
storage encryption disk modify -disk * -fips-key-id 0x0
```

.. Sanitize the disk:

+

```
storage encryption disk sanitize -disk * -force-all-states true
```

a| .. If you want to make the data on the disks inaccessible and you do not need to save the disks, destroy the disks:

.. If the storage system is configured as an HA pair, disable takeover.

.. Set the privilege level to advanced:

+

```
set -privilege advanced
```

.. Destroy the disks:

```
storage encryption disk destroy -disk * -force-all-states true
```

2+a| The storage system panics, leaving the system in a permanently disabled state with all data erased. To use the system again, you must reconfigure it.

a| Power is available to the KMIP server but not to the storage system

2+a|

.. Log in to the KMIP server.

.. Destroy all keys associated with the FIPS drives or SEDs that contain the data you want to prevent access to.

This prevents access to disk encryption keys by the storage system.

a| Power is not available to the KMIP server or the storage system

2+a|

Destroy the authentication item for the KMIP server (for example, the smart card). This prevents access to disk encryption keys by the storage system.

+

For complete command syntax, see the man pages.

:leveloffset: -1

= Return a FIPS drive or SED to service when authentication keys are lost

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

:hardbreaks-option:

[.lead]

The system treats a FIPS drive or SED as broken if you lose the authentication keys for it permanently and cannot retrieve them from the KMIP server. Although you cannot access or recover the data on the disk, you can take steps to make the SED's unused space available again for data.

.Before you begin

You must be a cluster administrator to perform this task.

.About this task

You should use this process only if you are certain that the authentication keys for the FIPS drive or SED are permanently lost and that you cannot recover them.

If the disks are partitioned, they must first be unpartitioned before you can start this process.

include::../_include/unpartition-disk.adoc[]

.Steps

. Return a FIPS drive or SED to service:

+

[cols="25,75"]

h| If the SEDS are... h| Use these steps...

a|

Not in FIPS-compliance mode, or in FIPS-compliance mode and the FIPS key is available

a|

.. Set the privilege level to advanced:

set -privilege advanced

.. Reset the FIPS key to the default manufacture secure ID 0x0:

storage encryption disk modify -fips-key-id 0x0 -disk *disk_id*

.. Verify the operation succeeded:

storage encryption disk show-status

If the operation failed, use the PSID process in this topic.

.. Sanitize the broken disk:

storage encryption disk sanitize -disk *disk_id*

Verify the operation succeeded with the command `storage encryption disk show-status` before proceeding to the next step.

.. Unfail the sanitized disk:

```
storage disk unfail -spare true -disk disk_id
```

.. Check whether the disk has an owner:

```
storage disk show -disk disk_id
```

.. If the disk does not have an owner, assign one, then unfail the disk again:

```
storage disk assign -owner node -disk disk_id
```

```
storage disk unfail -spare true -disk disk_id
```

.. Verify that the disk is now a spare and ready to be reused in an aggregate:

```
storage disk show -disk disk_id
```

a|

In FIPS-compliance mode, the FIPS key is not available, and the SEDs have a PSID printed on the label
a|

a. Obtain the PSID of the disk from the disk label.

b. Set the privilege level to advanced:

```
set -privilege advanced
```

c. Reset the disk to its factory-configured settings:

```
storage encryption disk revert-to-original-state -disk disk_id -psid  
disk_physical_secure_id
```

Verify the operation succeeded with the command `storage encryption disk show-status` before proceeding to the next step.

d. Unfail the sanitized disk:

```
storage disk unfail -spare true -disk disk_id
```

e. Check whether the disk has an owner:

```
storage disk show -disk disk_id
```

f. If the disk does not have an owner, assign one, then unfail the disk again:

```
storage disk assign -owner node -disk disk_id
```

```
storage disk unfail -spare true -disk disk_id
```

g. Verify that the disk is now a spare and ready to be reused in an aggregate:

```
storage disk show -disk disk_id
```

For complete command syntax, see the man pages.

= Return a FIPS drive or SED to unprotected mode

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

[.lead]

A FIPS drive or SED is protected from unauthorized access only if the authentication key ID for the node is set to a value other than the default. You can return a FIPS drive or SED to unprotected mode by using the `storage encryption disk modify` command to set the key ID to the default.

If an HA pair is using encrypting SAS or NVMe drives (SED, NSE, FIPS), you must follow this process for all drives within the HA pair prior to initializing the system (boot options 4 or 9). Failure to do this may result in future data loss if the drives are repurposed.

.What you'll need

You must be a cluster administrator to perform this task.

.Steps

. Set the privilege level to advanced:

+

`set -privilege advanced`

. If a FIPS drive is running in FIPS-compliance mode, set the FIPS authentication key ID for the node back to the default MSID 0x0:

+

`storage encryption disk modify -disk disk_id -fips-key-id 0x0`

+

You can use the `security key-manager query` command to view key IDs.

+

`cluster1::> storage encryption disk modify -disk 2.10.11 -fips-key-id 0x0`

Info: Starting modify on 14 disks.

View the status of the operation by using the `storage encryption disk show-status` command.

+

Confirm the operation succeeded with the command:

+

`storage encryption disk show-status`

+

Repeat the `show-status` command until the numbers in “Disks Begun” and “Disks Done” are the same.

+

`cluster1:: storage encryption disk show-status`

FIPS Latest Start Execution Disks Disks Disks

If you plan to continue using external key management after disconnecting a KMIP server, make sure another KMIP server is available to serve authentication keys.

Step

1. Disconnect a KMIP server from the current node:

For this ONTAP version...	Use this command...
ONTAP 9.6 and later	<code>security key-manager external remove-servers -vserver SVM -key-servers host_name IP_address:port,...</code>
ONTAP 9.5 and earlier	<code>security key-manager delete -address key_management_server_ipaddress</code>

In a MetroCluster environment, you must repeat these commands on both clusters for the admin SVM.

For complete command syntax, see the man pages.

The following ONTAP 9.6 command disables the connections to two external key management servers for `cluster1`, the first named `ks1`, listening on the default port 5696, the second with the IP address 10.0.0.20, listening on port 24482:

```
cluster1::> security key-manager external remove-servers -vserver cluster-1 -key-servers ks1,10.0.0.20:24482
```

= Modify external key management server properties
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

Beginning with ONTAP 9.6, you can use the `security key-manager external modify-server` command to change the I/O timeout and user name of an external key management server.

Before you begin

- You must be a cluster or SVM administrator to perform this task.
- Advanced privileges are required for this task.
- In a MetroCluster environment, you must repeat these steps on both clusters for the admin SVM.

Steps

1. On the storage system, change to advanced privilege level:

```
set -privilege advanced
```

2. Modify external key manager server properties for the cluster:

```
security key-manager external modify-server -vserver admin_SVM -key-server host_name|IP_address:port,... -timeout 1...60 -username user_name
```

The timeout value is expressed in seconds. If you modify the user name, you are prompted to enter a new password. If you run the command at the cluster login prompt, *admin_SVM* defaults to the admin SVM of the current cluster. You must be the cluster administrator to modify external key manager server properties.

+

The following command changes the timeout value to 45 seconds for the *cluster1* external key management server listening on the default port 5696:

+

```
cluster1::> security key-manager external modify-server -vserver
cluster1 -key-server ks1.local -timeout 45
```

1. Modify external key manager server properties for an SVM (NVE only):

```
security key-manager external modify-server -vserver SVM -key-server
host_name|IP_address:port,... -timeout 1...60 -username user_name
```

The timeout value is expressed in seconds. If you modify the user name, you are prompted to enter a new password. If you run the command at the SVM login prompt, *SVM* defaults to the current SVM. You must be the cluster or SVM administrator to modify external key manager server properties.

+

The following command changes the username and password of the `svm1` external key management server listening on the default port 5696:

+

```
svml::> security key-manager external modify-server -vserver svml1 -key  
-server ks1.local -username svmluser  
Enter the password:  
Reenter the password:
```

1. Repeat the last step for any additional SVMs.

= Transition to external key management from onboard key management

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

If you want to switch to external key management from onboard key management, you must delete the onboard key management configuration before you can enable external key management.

What you'll need

- For hardware-based encryption, you must reset the data keys of all FIPS drives or SEDs to the default value.

[Returning a FIPS drive or SED to unprotected mode](#)

- For software-based encryption, you must unencrypt all volumes.

[Unencrypting volume data](#)

- You must be a cluster administrator to perform this task.

Step

1. Delete the onboard key management configuration for a cluster:

For this ONTAP version...	Use this command...
ONTAP 9.6 and later	<code>security key-manager onboard disable -vserver SVM</code>
ONTAP 9.5 and earlier	<code>security key-manager delete-key-database</code>

For complete command syntax, see the [ONTAP manual pages](#).

= Transition to onboard key management from external key management

:icons: font

```
:relative_path: ./encryption-at-rest/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/
```

If you want to switch to onboard key management from external key management, you must delete the external key management configuration before you can enable onboard key management.

Before you begin

- For hardware-based encryption, you must reset the data keys of all FIPS drives or SEDs to the default value.

[Returning a FIPS drive or SED to unprotected mode](#)

- You must have deleted all external key manager connections.

[Deleting an external key manager connection](#)

- You must be a cluster administrator to perform this task.

== Procedure

1. Change to the advanced privilege level:

```
set -privilege advanced
```

2. Use the command:

```
security key-manager external disable -vserver admin_SVM
```

In a MetroCluster environment, you must repeat the command on both clusters for the admin SVM.

Use the command:

```
security key-manager delete-kmip-config
```

= What happens when key management servers are not reachable during the boot process

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

ONTAP takes certain precautions to avoid undesired behavior in the event that a storage system configured for NSE cannot reach any of the specified key management servers during the boot process.

If the storage system is configured for NSE, the SEDs are rekeyed and locked, and the SEDs are powered on, the storage system must retrieve the required authentication keys from the key management servers to authenticate itself to the SEDs before it can access the data.

The storage system attempts to contact the specified key management servers for up to three hours. If the storage system cannot reach any of them after that time, the boot process stops and the storage system halts.

If the storage system successfully contacts any specified key management server, it then attempts to establish an SSL connection for up to 15 minutes. If the storage system cannot establish an SSL connection with any specified key management server, the boot process stops and the storage system halts.

While the storage system attempts to contact and connect to key management servers, it displays detailed information about the failed contact attempts at the CLI. You can interrupt the contact attempts at any time by pressing Ctrl-C.

As a security measure, SEDs allow only a limited number of unauthorized access attempts, after which they disable access to the existing data. If the storage system cannot contact any specified key management servers to obtain the proper authentication keys, it can only attempt to authenticate with the default key which leads to a failed attempt and a panic. If the storage system is configured to automatically reboot in case of a panic, it enters a boot loop which results in continuous failed authentication attempts on the SEDs.

Halting the storage system in these scenarios is by design to prevent the storage system from entering a boot loop and possible unintended data loss as a result of the SEDs locked permanently due to exceeding the safety limit of a certain number of consecutive failed authentication attempts. The limit and the type of lockout protection depends on the manufacturing specifications and type of SED:

SED type	Number of consecutive failed authentication attempts resulting in lockout	Lockout protection type when safety limit is reached
HDD	1024	Permanent. Data cannot be recovered, even when the proper authentication key becomes available again.

X440_PHM2800MCTO 800GB NSE SSDs with firmware revisions NA00 or NA01	5	Temporary. Lockout is only in effect until disk is power-cycled.
X577_PHM2800MCTO 800GB NSE SSDs with firmware revisions NA00 or NA01	5	Temporary. Lockout is only in effect until disk is power-cycled.
X440_PHM2800MCTO 800GB NSE SSDs with higher firmware revisions	1024	Permanent. Data cannot be recovered, even when the proper authentication key becomes available again.
X577_PHM2800MCTO 800GB NSE SSDs with higher firmware revisions	1024	Permanent. Data cannot be recovered, even when the proper authentication key becomes available again.
All other SSD models	1024	Permanent. Data cannot be recovered, even when the proper authentication key becomes available again.

For all SED types, a successful authentication resets the try count to zero.

If you encounter this scenario where the storage system is halted due to failure to reach any specified key management servers, you must first identify and correct the cause for the communication failure before you attempt to continue booting the storage system.

= Disable encryption by default with ONTAP 9.7 and later

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

Beginning with ONTAP 9.7, aggregate and volume encryption is enabled by default if you have a volume encryption (VE) license and use an onboard or external key manager. You can disable encryption by default for the entire cluster, if required.

What you'll need

You must be a cluster administrator to perform this task, or an SVM administrator to whom the cluster administrator has delegated authority.

Step

1. To disable encryption by default for the entire cluster in ONTAP 9.7 or later, run the following command:

```
options -option-name encryption.data_at_rest_encryption.disable_by_default
-option-value on
```

= Data protection and disaster recovery

```

The topics in this section show you how to configure and manage data protection with System Manager in ONTAP 9.7 and later releases.

If you are using System Manager in ONTAP 9.7 or earlier, see [ONTAP System Manager Classic documentation](#)

Protect your data by creating and managing Snapshot copies, mirrors, vaults, and mirror-and-vault relationships.

SnapMirror is disaster recovery technology, designed for failover from primary storage to secondary storage at a geographically remote site. As its name implies, SnapMirror creates a replica, or mirror, of your working data in secondary storage from which you can continue to serve data in the event of a catastrophe at the primary site.

A *vault* is designed for disk-to-disk Snapshot copy replication for standards compliance and other governance-related purposes. In contrast to a SnapMirror relationship, in which the destination usually contains only the Snapshot copies currently in the source volume, a vault destination typically retains point-in-time Snapshot copies created over a much longer period.

Beginning with ONTAP 9.10.1, you can create data protection relationships between S3 buckets using S3 SnapMirror. Destination buckets can be on local or remote ONTAP systems, or on non-ONTAP systems such as StorageGRID and AWS. For more information, see [S3 SnapMirror overview](#).

= Create custom data protection policies

```
:toc: macro
```

```
:toclevels: 1
```

```
:hardbreaks:
```

```
:icons: font
```

```
:linkatrrs:
```

```
:relative_path: ./
```

```
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/
```

You can create custom data protection policies with System Manager when the existing default protection policies are not appropriate for your needs. Beginning with ONTAP 9.11.1, you can use System Manager to create custom mirror and vault policies, to display and select legacy policies. This capability is also available in ONTAP 9.8P12 and later patches of ONTAP 9.8.

Create custom protection policies on both the source and destination cluster.

Steps

1. Click **Protection > Local Policy Settings**.
2. Under **Protection Policies**, click →.
3. In the **Protection Policies** pane, click + Add .
4. Enter the new policy name, and select the policy scope.
5. Choose a policy type. To add a vault-only or mirror-only policy, choose **Asynchronous**, and click **Use a legacy policy type**.
6. Complete the required fields.
7. Click **Save**.
8. Repeat these steps on the other cluster.

= Configure Snapshot copies

```
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ../
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/../encryption-at-rest/../media/
```

You can create Snapshot copy policies to specify the maximum number of Snapshot copies that are automatically created and how frequently they are created. The policy specifies when to create Snapshot copies, how many copies to retain, and how to name them.

This procedure creates a Snapshot copy policy on the local cluster only.

Steps

1. Click **Protection > Overview > Local Policy Settings**.
2. Under **Snapshot Policies**, click →, and then click + Add .
3. Type the policy name, select the policy scope, and under **Schedules**, click + Add to enter the schedule details.

= Calculate reclaimable space before deleting Snapshot copies

```
:icons: font
:relative_path: ../
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/../encryption-at-rest/../media/
```

Beginning with ONTAP 9.10.1, you can use System Manager to select Snapshot copies you want to delete and calculate the reclaimable space before you delete them.

Steps

1. Click **Storage > Volumes**.
2. Select the volume from which you want to delete Snapshot copies.
3. Click **Snapshot Copies**.

4. Select one or more Snapshot copies.

5. Click **Calculate Reclaimable Space**.

= Enable or disable client access to Snapshot copy directory

:icons: font

:relative_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest./media/

Beginning with ONTAP 9.10.1, you can use System Manager to enable or disable client systems to access to a Snapshot copy directory on a volume. Enabling access makes the Snapshot copy directory visible to clients and allows Windows clients to map a drive to the Snapshot copies directory to view and access its contents.

You can enable or disable access to a volume's Snapshot copy directory by editing the volume settings or by editing the volume's share settings.

== Enable or disable client access to Snapshot copy directory by editing a volume

The Snapshot copy directory on a volume is accessible to clients by default.

Steps

1. Click **Storage > Volumes**.

2. Select the volume containing the Snapshot copies directory you want to either show or hide.

3. Click  and select **Edit**.

4. In the **Snapshot Copies (Local) Settings** section, select or deselect **Show the Snapshot copies directory to clients**.

5. Click **Save**.

== Enable or disable client access to Snapshot copy directory by editing a share

The Snapshot copy directory on a volume is accessible to clients by default.

Steps

1. Click **Storage > Shares**.

2. Select the volume containing the Snapshot copies directory you want to either show or hide.

3. Click  and select **Edit**.

4. In the **Share Properties** section, select or deselect **Allow clients to access Snapshot copies directory**.

5. Click **Save**.

= Recover from Snapshot copies

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest./media/

You can recover a volume to an earlier point in time by restoring from a Snapshot copy.

This procedure restores a volume from a Snapshot copy.

Steps

1. Click **Storage** and select a volume.
2. Under **Snapshot Copies**, click next to the Snapshot copy you want to restore, and select **Restore**.

= Prepare for mirroring and vaulting

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest./media/

You can protect your data by replicating it to a remote cluster for data backup and disaster recovery purposes.

Several default protection policies are available. You must have created your protection policies if you want to use custom policies.

Steps

1. In the local cluster, click **Protection > Overview**.
2. Expand **Intercluster Settings**. Click **Add Network Interfaces** and add intercluster network interfaces for the cluster.
Repeat this step on the remote cluster.
3. In the remote cluster, click **Protection > Overview**. Click in the Cluster Peers section and click **Generate Passphrase**.
4. Copy the generated passphrase and paste it in the local cluster.
5. In the local cluster, under Cluster Peers, click **Peer Clusters** and peer the local and remote clusters.
6. Optionally, under Storage VM Peers, click and then **Peer Storage VMs** to peer the storage VMs.
7. Click **Protect Volumes** to protect your volumes. To protect your LUNs, click **Storage > LUNs**, select a LUN to protect, and then click **Protect**.

Select the protection policy based on the type of data protection you need.

8. To verify the volumes and LUNs are successfully protected from the local cluster, click **Storage > Volumes** or **Storage > LUNs** and, expand the volume/LUN view.

== Other ways to do this in ONTAP

To perform these tasks with...	See this content...
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume disaster recovery preparation overview
The ONTAP command line interface	Create a cluster peer relationship

= Configure mirrors and vaults

:toc: macro

:toplevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

Create a mirror and vault of a volume to protect data in case of a disaster and to have multiple archived versions of data to which you can roll back. Beginning with ONTAP 9.11.1, you can use System Manager to select pre-created and custom mirror and vault policies, to display and select legacy policies, and to override the transfer schedules defined in a protection policy when protecting volumes and storage VMs. This capability is also available in ONTAP 9.8P12 and later patches of ONTAP 9.8.

If you are using ONTAP 9.8P12 or later ONTAP 9.8 patch release and you configured SnapMirror using System Manager, you should use ONTAP 9.9.1P13 or later and ONTAP 9.10.1P10 or later patch releases if you plan to upgrade to ONTAP 9.9.1 or ONTAP 9.10.1 releases.

This procedure creates a data protection policy on a remote cluster. The source cluster and destination cluster use intercluster network interfaces for exchanging data. The procedure assumes the [intercluster network interfaces are created and the clusters containing the volumes are peered](#) (paired). You can also peer storage VMs for data protection; however, if storage VMs are not peered, but permissions are enabled, storage VMs are automatically peered when the protection relationship is created.

Steps

1. Select the volume or LUN to protect: click **Storage > Volumes** or **Storage > LUNs**, and then click the desired volume or LUN name.
2. Click **Protect**.
3. Select the destination cluster and storage VM.
4. The asynchronous policy is selected by default. To select a synchronous policy, click **More Options**.
5. Click **Protect**.
6. Click the **SnapMirror (Local or Remote)** tab for the selected volume or LUN to verify that protection is set up correctly.

== Other ways to do this in ONTAP

To perform these tasks with...	See this content...
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume backup using SnapVault overview
The ONTAP command line interface	Create a replication relationship

= Resynchronize a protection relationship

:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

When your original source volume is available again after a disaster, you can resynchronize data from the destination volume and reestablish the protection relationship.

This procedure replaces the data in the original source volume in an asynchronous relationship so that you can start serving data from the original source volume again and resume the original protection relationship.

Steps

1. Click **Protection > Relationships** and then click the broken off relationship you want to resynchronize.

2. Click  and then select **Resync**.
3. Under **Relationships**, monitor the resynchronization progress by checking the relationship state. The state changes to "Mirrored" when resynchronization is complete.

= Restore a volume from an earlier Snapshot copy

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

When data in a volume is lost or corrupted, you can roll back your data by restoring from an earlier Snapshot copy.

This procedure replaces the current data on the source volume with data from an earlier Snapshot copy version. You should perform this task on the destination cluster.

Steps

1. Click **Protection > Relationships**, and then click the source volume name.
2. Click  and then select **Restore**.
3. Under **Source**, the source volume is selected by default. Click **Other Volume** if you want to choose a volume other than the source.
4. Under **Destination**, choose the Snapshot copy you want to restore.
5. If your source and destination are located on different clusters, on the remote cluster, click **Protection > Relationships** to monitor the restore progress.

== Other ways to do this in ONTAP

To perform these tasks with...	See this content...
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume restore using SnapVault overview
The ONTAP command line interface	Restore the contents of a volume from a SnapMirror destination

= Recover from Snapshot copies

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

You can recover a volume to an earlier point in time by restoring from a Snapshot copy.

This procedure restores a volume from a Snapshot copy.

Steps

1. Click **Storage** and select a volume.
2. Under **Snapshot Copies**, click  next to the Snapshot copy you want to restore, and select **Restore**.

= Restore to a new volume

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

Beginning with ONTAP 9.8, you can use System Manager to restore backed up data on the destination volume to a volume other than the original source.

When you restore to a different volume, you can select an existing volume, or you can create a new volume.

Steps

1. Select the desired protection relationship: click **Protection > Relationships**.
2. Click  and click **Restore**.
3. In the **Source** section, select **Other Volume** and select the cluster and Storage VM.
4. Select either **Existing volume** or **Create a new volume**.
5. If you are creating a new volume, enter the volume name.
6. In the **Destination** section, select the Snapshot copy to restore.
7. Click **Save**.
8. Under **Relationships**, monitor the restore progress by viewing **Transfer Status** for the relationship.

= Reverse Resynchronizing a Protection Relationship

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

Beginning with ONTAP 9.8, you can use System Manager to perform a reverse resynchronization operation to delete an existing protection relationship and reverse the functions of the source and destination volumes. Then you use the destination volume to serve data while you repair or replace the source, update the source, and reestablish the original configuration of the systems.

System Manager does not support reverse resynchronization with intracluster relationships. You can use the ONTAP CLI to perform reverse sync operations with intracluster relationships.

When you perform a reverse resynch operation, any data on the source volume that is newer than the data in the common Snapshot copy is deleted.

Steps

1. Select the desired protection relationship: click **Protection > Relationships**.
2. Click  and click **Reverse Resync**.
3. Under **Relationships**, monitor the reverse resynchronization progress by viewing **Transfer Status** for the relationship.

= Serve data from a SnapMirror destination

:toc: macro

:toclevels: 1

:hardbreaks:

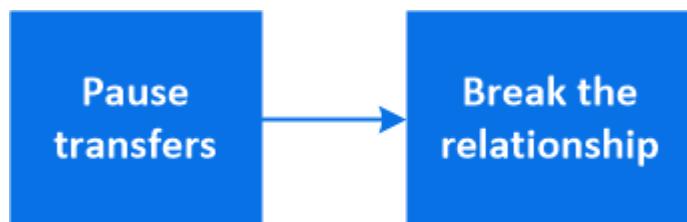

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

To serve data from a mirror destination when a source becomes unavailable, stop scheduled transfers to the destination, and then break the SnapMirror relationship to make the destination writable.

Steps

1. Select the desired protection relationship: click **Protection > Relationships**, and then click the desired volume name.
2. Click .
3. Stop scheduled transfers : click **Pause**.
4. Make the destination writable: click **Break**.
5. Go to the main **Relationships** page to verify that the relationship state displays as "broken off".

Next steps:

When the disabled source volume is available again, you should resynchronize the relationship to copy the current data to the original source volume. This process replaces the data on the original source volume.

== Other ways to do this in ONTAP

To perform these tasks with...	See this content...
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume disaster recovery overview

To perform these tasks with...	See this content...
The ONTAP command line interface	Activate the destination volume

= Configure storage VM disaster recovery
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrs:
:relative_path: ./
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

Using System Manager, you can create an storage VM disaster recovery (storage VM DR) relationship to replicate one storage VM configuration to another. In the event of a disaster at the primary site, you can quickly activate the destination storage VM.

Complete this procedure from the destination. If you need to create a new protection policy, for instance, when your source storage VM has SMB configured, you should use System Manager to create the policy and select the **Copy source storage VM configuration** option in the **Add Protection Policy** window. For details see [Create custom data protection policies](#).

Steps

1. On the destination cluster, click **Protection > Relationships**.
2. Under **Relationships**, click Protect and choose **Storage VMs (DR)**.
3. Select a protection policy. If you created a custom protection policy, select it, then choose the source cluster and storage VM you want to replicate. You can also create a new destination storage VM by entering a new storage VM name.
4. Click **Save**.

= Serve data from an SVM DR destination
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrs:
:relative_path: ./
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

Beginning with ONTAP 9.8, you can use System Manager to activate a destination storage VM after a disaster. Activating the destination storage VM makes the SVM destination volumes writable and enables you to serve data to clients.

Steps

1. If the source cluster is accessible, verify that the SVM is stopped: navigate to **Storage > Storage VMs** and check the **State** column for the SVM.
2. If the source SVM state is "Running", stop it: select  and choose **Stop**.
3. On the destination cluster, locate the desired protection relationship: navigate to **Protection > Relationships**.

4. Click  and choose **Activate Destination Storage VM**.

= Reactivate a source storage VM

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

Beginning with ONTAP 9.8, you can use System Manager to reactivate a source storage VM after a disaster. Reactivating the source storage VM stops the destination storage VM, and it reenables replication from the source to the destination.

About this task

When you reactivate the source storage VM, System Manager performs the following operations in the background:

- Creates a reverse SVM DR relationship from the original destination to original source using SnapMirror resync
- Stops the destination SVM
- Updates the SnapMirror relationship
- Breaks the SnapMirror relationship
- Restarts the original SVM
- Issues a SnapMirror resync of the original source back to the original destination
- Cleans up the SnapMirror relationships

Steps

1. Select the desired protection relationship: click **Protection > Relationships**.

2. Click  and click **Reactivate Source Storage VM**.

3. Under **Relationships**, monitor the source reactivation progress by viewing **Transfer Status** for the protection relationship.

= Resynchronize a destination storage VM

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

Beginning with ONTAP 9.8, you can use System Manager to resynchronize the data and configuration details from the source storage VM to the destination storage VM in a broken protection relationship and reestablish the relationship.

ONTAP 9.11.1 introduces an option to bypass a full data warehouse rebuild when you perform a disaster recovery rehearsal, enabling you to return to production faster.

You perform the resync operation only from the destination of the original relationship. The resync deletes any data in the destination storage VM that is newer than the data in the source storage VM.

Steps

1. Select the desired protection relationship: click **Protection > Relationships**.
2. Optionally, select **Perform a quick resync** to bypass a full data warehouse rebuild during a disaster recovery rehearsal.
3. Click  and click **Resync**.
4. Under **Relationships**, monitor the resynchronization progress by viewing **Transfer Status** for the relationship.

= Back up data to the cloud using SnapMirror

:toc: macro

:toplevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest./media/

Beginning with ONTAP 9.9.1, you can back up your data to the cloud and to restore your data from cloud storage to a different volume by using System Manager. You can use either StorageGRID or ONTAP S3 as your cloud object store.

Before using the SnapMirror Cloud feature, you should request a SnapMirror Cloud API license key from the NetApp Support Site: [Request SnapMirror Cloud API license key](#).

Following the instructions, you should provide a simple description of your business opportunity and request the API key by sending an email to the provided email address. You should receive an email response within 24 hours with further instructions on how to acquire the API key.

== Add a cloud object store

Before you configure SnapMirror Cloud backups, you need to add a StorageGRID or ONTAP S3 cloud object store.

Steps

1. Click **Protection > Overview > Cloud Object Stores**.
2. Click  **Add**.

== Back up using the default policy

You can quickly configure a SnapMirror Cloud backup for an existing volume using the default cloud protection policy, DailyBackup.

Steps

1. Click **Protection > Overview** and select **Back Up Volumes to Cloud**.
2. If this is your first time backing up to the cloud, enter your SnapMirror Cloud API license key in the license field as indicated.
3. Click **Authenticate and Continue**.
4. Select a source volume.

5. Select a cloud object store.

6. Click **Save**.

== Create a custom cloud backup policy

If you do not want to use the default DailyBackup cloud policy for your SnapMirror Cloud backups, you can create your own policy.

Steps

1. Click **Protection > Overview > Local Policy Settings** and select **Protection Policies**.
2. Click **Add** and enter the new policy details.
3. In the **Policy Type** section, select **Back up to Cloud** to indicate that you are creating a cloud policy.
4. Click **Save**.

== Create a backup from the **Volumes** page

You can use the System Manager **Volumes** page to when you want to select and create cloud backups for multiple volumes at one time or when you want to use a custom protection policy.

Steps

1. Click **Storage > Volumes**.
2. Select the volumes you want to back up to the cloud, and click **Protect**.
3. In the **Protect Volume** window, click **More Options**.
4. Select a policy.

You can select the default policy, DailyBackup, or a custom cloud policy you created.

5. Select a cloud object store.

6. Click **Save**.

== Restore from the cloud

You can use System Manager to restore backed up data from cloud storage to a different volume on the source cluster.

Steps

1. Click **Storage > Volumes**.
2. Select the **Back Up to Cloud** tab.
3. Click  next to the source volume you want to restore, and select **Restore**.
4. Under **Source**, select a storage VM and then enter the name of the volume to which you want the data restored.
5. Under **Destination**, select the Snapshot copy you want to restore.
6. Click **Save**.

== Delete a SnapMirror Cloud relationship

You can use System Manager to delete a cloud relationship.

Steps

1. Click **Storage > Volumes** and select the volume you want to delete.
2. Click  next to the source volume and select **Delete**.
3. Select **Delete the cloud object store endpoint (optional)** if you want to delete the cloud object store endpoint.
4. Click **Delete**.

== Remove a cloud object store

You can use System Manager to remove a cloud object store if it is not part of a cloud backup relationship. When a cloud object store is part of a cloud backup relationship, it cannot be deleted.

Steps

1. Click **Protection > Overview > Cloud Object Stores**.
2. Select the object store you want to delete, click  and select **Delete**.

= Back up data using Cloud Backup

```
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ../
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/
```

Beginning with ONTAP 9.9.1, you can use System Manager to back up data in the cloud using Cloud Backup.

Cloud Backup supports FlexVol read-write volumes and data-protection (DP) volumes. FlexGroup volumes and SnapLock volumes are not supported.

Before you begin

You should perform the following procedures to establish an account in BlueXP. For the service account, you need to create the role as "Account Admin". (Other service account roles do not have the required privileges needed to establish a connection from System Manager.)

1. [Create an account in BlueXP](#).
2. [Create a connector in BlueXP](#) with one of the following cloud providers:
 - Microsoft Azure
 - Amazon Web Services (AWS)
 - Google Cloud Platform (GCP)
 - StorageGrid (ONTAP 9.10.1)

Beginning with ONTAP 9.10.1, you can select StorageGrid as a cloud backup provider, but only if BlueXP is deployed on premises. The BlueXP connector must be installed on premises and available through the BlueXP software-as-a-service (SaaS) application.

3. [Subscribe to Cloud Backup Service in BlueXP](#) (requires the appropriate license).

4. Generate an access key and a secret key using BlueXP.

== Register the cluster with BlueXP

You can register the cluster with BlueXP by using either BlueXP or System Manager.

Steps

1. In System Manager, go to **Protection Overview**.
2. Under **Cloud Backup Service**, provide the following details:
 - Client ID
 - Client secret key
3. Select **Register and Continue**.

== Enable Cloud Backup

After the cluster is registered with BlueXP, you need to enable the Cloud Backup and initiate the first backup to the cloud.

Steps

1. In System Manager, click **Protection > Overview**, then scroll to the **Cloud Backup Service** section.
2. Enter the **Client ID** and **Client Secret**.

Beginning with ONTAP 9.10.1, you can learn about the cost of using the cloud by clicking **Learn more about the cost of using the cloud**.

3. Click **Connect and Enable Cloud Backup Service**.
4. On the **Enable Cloud Backup Service** page, provide the following details, depending on the provider you selected.

For this cloud provider...	Enter the following data...
Azure	<ul style="list-style-type: none">• Azure Subscription ID• Region• Resource group name (existing or new)
AWS	<ul style="list-style-type: none">• AWS Account ID• Access key• Secret key• Region
Google Cloud Project (GCP)	<ul style="list-style-type: none">• Google Cloud Project name• Google Cloud Access key• Google Cloud Secret key• Region

StorageGrid
(ONTAP 9.10.1 and later, and only for on-premises deployment of BlueXP)

- Server
- SG Access Key
- SG Secret Key

5. Select a **Protection policy**:

- **Existing policy:** Choose an existing policy.
- **New Policy:** Specify a name and set up a transfer schedule.

Beginning with ONTAP 9.10.1, you can specify whether you want to enable archiving with Azure or AWS.

If you enable archiving for a volume with Azure or AWS, you cannot disable the archiving.

If you enable archiving for Azure or AWS, specify the following:

- The number of days after which the volume is archived.
- The number of backups to retain in the archive. Specify “0” (zero) to archive up to the latest backup.
- For AWS, select the archive storage class.

6. Select the volumes you want to back up.

7. Select **Save**.

== Edit the protection policy used for Cloud Backup

You can change which protection policy is used with Cloud Backup.

Steps

1. In System Manager, click **Protection > Overview**, then scroll to the **Cloud Backup Service** section.
2. Click , then **Edit**.
3. Select a **Protection policy**:

- **Existing policy:** Choose an existing policy.
- **New Policy:** Specify a name and set up a transfer schedule.

Beginning with ONTAP 9.10.1, you can specify whether you want to enable archiving with Azure or AWS.

If you enable archiving for a volume with Azure or AWS, you cannot disable the archiving.

If you enable archiving for Azure or AWS, specify the following:

- The number of days after which the volume is archived.
- The number of backups to retain in the archive. Specify “0” (zero) to archive up to the latest backup.

- For AWS, select the archive storage class.

4. Select **Save**.

== Protect new volumes or LUNs on the cloud

When you create a new volume or LUN, you can establish a SnapMirror protection relationship that enables backing up to the cloud for the volume or LUN.

Before you begin

- You should have a SnapMirror license.
- Intercluster LIFs should be configured.
- NTP should be configured.
- Cluster must be running ONTAP 9.9.1.

About this task

You cannot protect new volumes or LUNs on the cloud for the following cluster configurations:

- The cluster cannot be in a MetroCluster environment.
- SVM-DR is not supported.
- FlexGroups cannot be backed up using Cloud Backup.

Steps

1. When provisioning a volume or LUN, on the **Protection** page in System Manager, select the checkbox labeled **Enable SnapMirror (Local or Remote)**.
2. Select the Cloud Backup policy type.
3. If the Cloud Backup is not enabled, select **Enable Cloud Backup Service**.

== Protect existing volumes or LUNs on the cloud

You can establish a SnapMirror protection relationship for existing volumes and LUNs.

Steps

1. Select an existing volume or LUN, and click **Protect**.
2. On the **Protect Volumes** page, specify **Backup using Cloud Backup Service** for the protection policy.
3. Click **Protect**.
4. On the **Protection** page, select the checkbox labeled **Enable SnapMirror (Local or Remote)**.
5. Select **Enable Cloud Backup Service**.

== Restore data from backup files

You can perform backup management operations, such as restoring data, updating relationships, and deleting relationships, only when using the BlueXP interface. Refer to [Restoring data from backup files](#) for more information.

= Cluster and SVM peering with the CLI

= Cluster and SVM peering overview with the CLI

:icons: font

```
:relative_path: ./peering/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/
```

You can create peer relationships between source and destination clusters and between source and destination storage virtual machines (SVMs). You must create peer relationships between these entities before you can replicate Snapshot copies using SnapMirror.

ONTAP 9.3 offers enhancements that simplify the way you configure peer relationships between clusters and SVMs. The cluster and SVMs peering procedures are available for all ONTAP 9 versions. You should use the appropriate procedure for your version of ONTAP.

You perform the procedures using the command-line interface (CLI), not System Manager or an automated scripting tool.

= Prepare for cluster and SVM peering

= Peering basics

:icons: font

```
:relative_path: ./peering/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/
```

You must create *peer relationships* between source and destination clusters and between source and destination SVMs before you can replicate Snapshot copies using SnapMirror. A peer relationship defines network connections that enable clusters and SVMs to exchange data securely.

Clusters and SVMs in peer relationships communicate over the intercluster network using *intercluster logical interfaces (LIFs)*. An intercluster LIF is a LIF that supports the "intercluster-core" network interface service and is typically created using the "default-intercluster" network interface service policy. You must create intercluster LIFs on every node in the clusters being peered.

Intercluster LIFs use routes that belong to the system SVM to which they are assigned. ONTAP automatically creates a system SVM for cluster-level communications within an IPspace.

Fan-out and cascade topologies are both supported. In a cascade topology, you need only create intercluster networks between the primary and secondary clusters and between the secondary and tertiary clusters. You need not create an intercluster network between the primary and the tertiary cluster.

It is possible (but not advisable) for an administrator to remove the intercluster-core service from the default-intercluster service policy. If this occurs, LIFs created using "default-intercluster" will not actually be intercluster LIFs. To confirm that the default-intercluster service policy contains the intercluster-core service, use the following command:

```
network interface service-policy show -policy default-intercluster
```

= Prerequisites for cluster peering

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

Before you set up cluster peering, you should confirm that the connectivity, port, IP address, subnet, firewall, and cluster-naming requirements are met.

== Connectivity requirements

Every intercluster LIF on the local cluster must be able to communicate with every intercluster LIF on the remote cluster.

Although it is not required, it is typically simpler to configure the IP addresses used for intercluster LIFs in the same subnet. The IP addresses can reside in the same subnet as data LIFs, or in a different subnet. The subnet used in each cluster must meet the following requirements:

- The subnet must belong to the broadcast domain that contains the ports that are used for intercluster communication.
- The subnet must have enough IP addresses available to allocate to one intercluster LIF per node.

For example, in a four-node cluster, the subnet used for intercluster communication must have four available IP addresses.

Each node must have an intercluster LIF with an IP address on the intercluster network.

Intercluster LIFs can have an IPv4 address or an IPv6 address.

ONTAP 9 enables you to migrate your peering networks from IPv4 to IPv6 by optionally allowing both protocols to be present simultaneously on the intercluster LIFs. In earlier releases, all intercluster relationships for an entire cluster were either IPv4 or IPv6. This meant that changing protocols was a potentially disruptive event.

== Port requirements

You can use dedicated ports for intercluster communication, or share ports used by the data network. Ports must meet the following requirements:

- All ports that are used to communicate with a given remote cluster must be in the same IPspace.
You can use multiple IPspaces to peer with multiple clusters. Pair-wise full-mesh connectivity is required only within an IPspace.
- The broadcast domain that is used for intercluster communication must include at least two ports per node so that intercluster communication can fail over from one port to another port.
Ports added to a broadcast domain can be physical network ports, VLANs, or interface groups (ifgrps).
- All ports must be cabled.
- All ports must be in a healthy state.
- The MTU settings of the ports must be consistent.

== Firewall requirements

Firewalls and the intercluster firewall policy must allow the following protocols:

- ICMP service
- TCP to the IP addresses of all the intercluster LIFs over the ports 10000, 11104, and 11105
- Bidirectional HTTPS between the intercluster LIFs

Although HTTPS is not required when you set up cluster peering using the CLI, HTTPS is required later if you use System Manager to configure data protection.

The default `intercluster` firewall policy allows access through the HTTPS protocol and from all IP addresses (0.0.0.0/0). You can modify or replace the policy if necessary.

Beginning with ONTAP 9.10.1, firewall policies are deprecated and wholly replaced with LIF service policies. For more information, see [Configure firewall policies for LIFs](#).

== Cluster requirement

Clusters must meet the following requirement:

- A cluster cannot be in a peer relationship with more than 255 clusters.

= Use shared or dedicated ports

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/./media/

You can use dedicated ports for intercluster communication, or share ports used by the data network. In deciding whether to share ports, you need to consider network bandwidth, the replication interval, and port availability.

You can share ports on one peered cluster while using dedicated ports on the other.

== Network bandwidth

If you have a high-speed network, such as 10 GbE, you might have enough local LAN bandwidth to perform replication using the same 10 GbE ports used for data access.

Even then, you should compare your available WAN bandwidth to your LAN bandwidth. If the available WAN bandwidth is significantly less than 10 GbE, you might need to use dedicated ports.

The one exception to this rule might be when all or many nodes in the cluster replicate data, in which case bandwidth utilization is typically spread across nodes.

If you are not using dedicated ports, the maximum transmission unit (MTU) size of the replication network should typically be the same as the MTU size of the data network.

== Replication interval

If replication takes place in off-peak hours, you should be able to use data ports for replication even without a 10-GbE LAN connection.

If replication takes place during normal business hours, you need to consider the amount of data that will be replicated and whether it requires so much bandwidth that it could cause contention with data protocols. If network utilization by data protocols (SMB, NFS, iSCSI) is above 50%, you should use dedicated ports for intercluster communication, to allow for non-degraded performance if node failover occurs.

== Port availability

If you determine that replication traffic is interfering with data traffic, you can migrate intercluster LIFs to any other intercluster-capable shared port on the same node.

You can also dedicate VLAN ports for replication. The bandwidth of the port is shared between all VLANs and the base port.

= Use custom IPspaces to isolate replication traffic

:icons: font

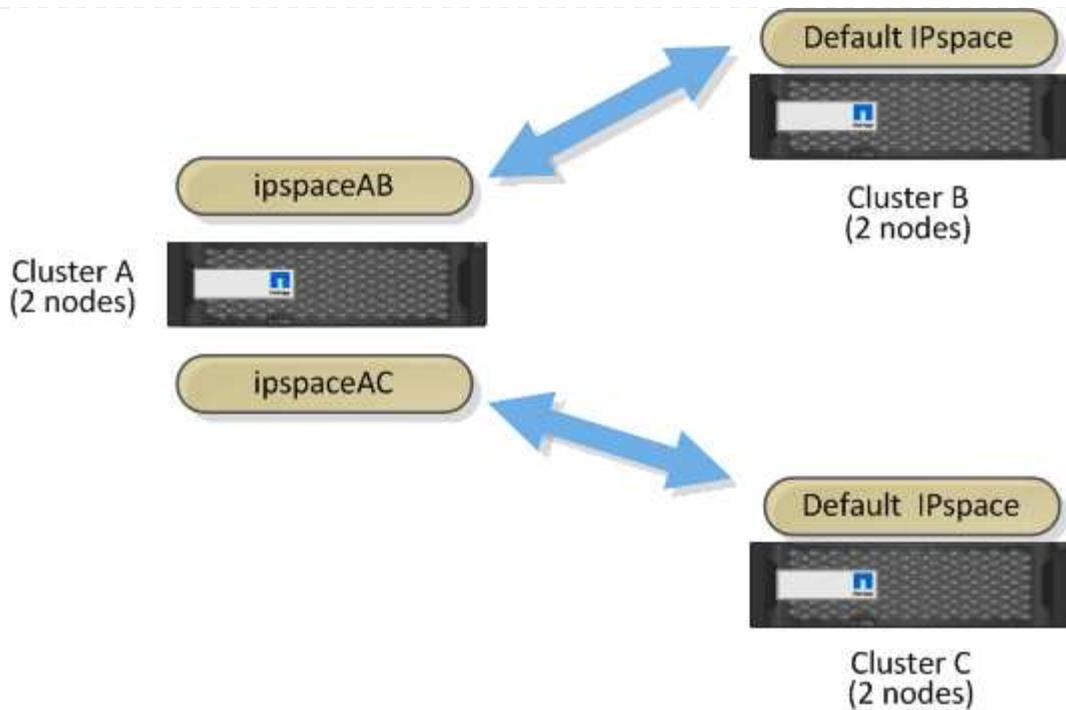

:relative_path: ./peering/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You can use custom IPspaces to separate the interactions that a cluster has with its peers. Called *designated intercluster connectivity*, this configuration allows service providers to isolate replication traffic in multitenant environments.

Suppose, for example, that you want replication traffic between Cluster A and Cluster B to be separated from replication traffic between Cluster A and Cluster C. To accomplish this, you can create two IPspaces on Cluster A.

One IPspace contains the intercluster LIFs that you use to communicate with Cluster B. The other contains the intercluster LIFs that you use to communicate with Cluster C, as shown in the following illustration.

For custom IPspace configuration, see the *Network Management Guide*.

= Configure intercluster LIFs

= Configure intercluster LIFs on shared data ports

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You can configure intercluster LIFs on ports shared with the data network. Doing so reduces the number of ports you need for intercluster networking.

Steps

1. List the ports in the cluster:

```
network port show
```

For complete command syntax, see the man page.

The following example shows the network ports in `cluster01`:

```

cluster01::> network port show
                                         Speed
                                         (Mbps)
Node    Port      IPspace      Broadcast Domain Link      MTU
Admin/Oper
-----
-----
cluster01-01
    e0a        Cluster       Cluster          up     1500
auto/1000
    e0b        Cluster       Cluster          up     1500
auto/1000
    e0c        Default       Default          up     1500
auto/1000
    e0d        Default       Default          up     1500
auto/1000
cluster01-02
    e0a        Cluster       Cluster          up     1500
auto/1000
    e0b        Cluster       Cluster          up     1500
auto/1000
    e0c        Default       Default          up     1500
auto/1000
    e0d        Default       Default          up     1500
auto/1000

```

2. Create intercluster LIFs on the system SVM:

Option	Description
In ONTAP 9.6 and later:	<code>network interface create -vserver <i>system_SVM</i> -lif <i>LIF_name</i> -service -policy default-intercluster -home -node <i>node</i> -home-port <i>port</i> -address <i>port_IP</i> -netmask <i>netmask</i></code>
In ONTAP 9.5 and earlier:	<code>network interface create -vserver <i>system_SVM</i> -lif <i>LIF_name</i> -role intercluster -home-node <i>node</i> -home -port <i>port</i> -address <i>port_IP</i> -netmask <i>netmask</i></code>

For complete command syntax, see the man page.

The following example creates intercluster LIFs `cluster01_icl01` and `cluster01_icl02`:

```

cluster01::> network interface create -vserver cluster01 -lif
cluster01_icl01 -service-
policy default-intercluster -home-node cluster01-01 -home-port e0c
-address 192.168.1.201
-netmask 255.255.255.0

cluster01::> network interface create -vserver cluster01 -lif
cluster01_icl02 -service-
policy default-intercluster -home-node cluster01-02 -home-port e0c
-address 192.168.1.202
-netmask 255.255.255.0

```

3. Verify that the intercluster LIFs were created:

Option	Description
In ONTAP 9.6 and later:	network interface show -service -policy default-intercluster
In ONTAP 9.5 and earlier:	network interface show -role intercluster

For complete command syntax, see the man page.

```

cluster01::> network interface show -service-policy default-
intercluster
          Logical      Status      Network      Current
Current Is
Vserver     Interface   Admin/Oper Address/Mask      Node
Port       Home
----- -----
----- -
cluster01
          cluster01_icl01
                  up/up      192.168.1.201/24    cluster01-01
e0c        true
          cluster01_icl02
                  up/up      192.168.1.202/24    cluster01-02
e0c        true

```

4. Verify that the intercluster LIFs are redundant:

Option	Description
In ONTAP 9.6 and later:	network interface show -service-policy default-intercluster -failover
In ONTAP 9.5 and earlier:	network interface show -role intercluster -failover

For complete command syntax, see the man page.

The following example shows that the intercluster LIFs `cluster01_icl01` and `cluster01_icl02` on the `e0c` port will fail over to the `e0d` port.

```
cluster01::> network interface show -service-policy default-
intercluster -failover
      Logical          Home          Failover
      Failover
Vserver   Interface      Node:Port      Policy      Group
-----  -----
-----  -----
cluster01
      cluster01_icl01  cluster01-01:e0c    local-only
      192.168.1.201/24
                           Failover Targets: cluster01-01:e0c,
                                         cluster01-01:e0d
      cluster01_icl02  cluster01-02:e0c    local-only
      192.168.1.201/24
                           Failover Targets: cluster01-02:e0c,
                                         cluster01-02:e0d
```

= Configure intercluster LIFs on dedicated ports

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can configure intercluster LIFs on dedicated ports. Doing so typically increases the available bandwidth for replication traffic.

Steps

1. List the ports in the cluster:

```
network port show
```

For complete command syntax, see the man page.

The following example shows the network ports in `cluster01`:

cluster01::> network port show						Speed (Mbps)
Node	Port	IPspace	Broadcast	Domain	Link	MTU
Admin/Oper						
<hr/>						
<hr/>						
cluster01-01						
	e0a	Cluster	Cluster		up	1500
auto/1000						
	e0b	Cluster	Cluster		up	1500
auto/1000						
	e0c	Default	Default		up	1500
auto/1000						
	e0d	Default	Default		up	1500
auto/1000						
	e0e	Default	Default		up	1500
auto/1000						
	e0f	Default	Default		up	1500
auto/1000						
cluster01-02						
	e0a	Cluster	Cluster		up	1500
auto/1000						
	e0b	Cluster	Cluster		up	1500
auto/1000						
	e0c	Default	Default		up	1500
auto/1000						
	e0d	Default	Default		up	1500
auto/1000						
	e0e	Default	Default		up	1500
auto/1000						
	e0f	Default	Default		up	1500
auto/1000						

2. Determine which ports are available to dedicate to intercluster communication:

network interface show -fields home-port,curr-port

For complete command syntax, see the man page.

The following example shows that ports e0e and e0f have not been assigned LIFs:

```

cluster01::> network interface show -fields home-port,curr-port
vserver lif           home-port curr-port
-----
Cluster cluster01-01_clus1    e0a      e0a
Cluster cluster01-01_clus2    e0b      e0b
Cluster cluster01-02_clus1    e0a      e0a
Cluster cluster01-02_clus2    e0b      e0b
cluster01
    cluster_mgmt        e0c      e0c
cluster01
    cluster01-01_mgmt1   e0c      e0c
cluster01
    cluster01-02_mgmt1   e0c      e0c

```

3. Create a failover group for the dedicated ports:

```

network interface failover-groups create -vserver system_SVM -failover
-group failover_group -targets physical _or_logical_ports

```

The following example assigns ports **e0e** and **e0f** to the failover group **intercluster01** on the system SVM **cluster01**:

```

cluster01::> network interface failover-groups create -vserver
cluster01 -failover-group
intercluster01 -targets
cluster01-01:e0e,cluster01-01:e0f,cluster01-02:e0e,cluster01-02:e0f

```

4. Verify that the failover group was created:

```
network interface failover-groups show
```

For complete command syntax, see the man page.

```

cluster01::> network interface failover-groups show
                               Failover
Vserver          Group          Targets
-----
----- Cluster
Cluster
cluster01-01:e0a, cluster01-
01:e0b,
cluster01-02:e0a, cluster01-02:e0b
cluster01
Default
cluster01-01:e0c, cluster01-
01:e0d,
cluster01-02:e0c, cluster01-
02:e0d,
cluster01-01:e0e, cluster01-01:e0f
cluster01-02:e0e, cluster01-02:e0f
intercluster01
cluster01-01:e0e, cluster01-01:e0f
cluster01-02:e0e, cluster01-02:e0f

```

5. Create intercluster LIFs on the system SVM and assign them to the failover group.

Option	Description
In ONTAP 9.6 and later:	<code>network interface create -vserver <i>system_SVM</i> -lif <i>LIF_name</i> -service -policy default-intercluster -home -node <i>node</i> -home- port <i>port</i> -address <i>port_IP</i> -netmask <i>netmask</i> -failover -group <i>failover_group</i></code>
In ONTAP 9.5 and earlier:	<code>network interface create -vserver <i>system_SVM</i> -lif <i>LIF_name</i> -role intercluster -home-node <i>node</i> -home -port <i>port</i> -address <i>port_IP</i> -netmask <i>netmask</i> -failover-group <i>failover_group</i></code>

For complete command syntax, see the man page.

The following example creates intercluster LIFs `cluster01_icl01` and `cluster01_icl02` in the failover group `intercluster01`:

```

cluster01::> network interface create -vserver cluster01 -lif
cluster01_icl01 -service-
policy default-intercluster -home-node cluster01-01 -home-port e0e
-address 192.168.1.201
-netmask 255.255.255.0 -failover-group intercluster01

cluster01::> network interface create -vserver cluster01 -lif
cluster01_icl02 -service-
policy default-intercluster -home-node cluster01-02 -home-port e0e
-address 192.168.1.202
-netmask 255.255.255.0 -failover-group intercluster01

```

6. Verify that the intercluster LIFs were created:

Option	Description
In ONTAP 9.6 and later:	network interface show -service -policy default-intercluster
In ONTAP 9.5 and earlier:	network interface show -role intercluster

For complete command syntax, see the man page.

```

cluster01::> network interface show -service-policy default-
intercluster
          Logical      Status      Network      Current
Current Is
Vserver     Interface   Admin/Oper Address/Mask      Node
Port       Home
----- -----
----- -
cluster01
          cluster01_icl01
                  up/up      192.168.1.201/24    cluster01-01
e0e        true
          cluster01_icl02
                  up/up      192.168.1.202/24    cluster01-02
e0f        true

```

7. Verify that the intercluster LIFs are redundant:

Option	Description
In ONTAP 9.6 and later:	network interface show -service -policy default-intercluster -failover
In ONTAP 9.5 and earlier:	network interface show -role intercluster -failover

For complete command syntax, see the man page.

The following example shows that the intercluster LIFs `cluster01_icl01` and `cluster01_icl02` on the SVM₀e port will fail over to the e0f port.

```
cluster01::> network interface show -service-policy default-
intercluster -failover
      Logical          Home          Failover
      Failover
Vserver  Interface       Node:Port        Policy      Group
-----  -----
-----  -----
cluster01
      cluster01_icl01  cluster01-01:e0e   local-only
intercluster01
      Failover Targets:  cluster01-01:e0e,
                           cluster01-01:e0f
      cluster01_icl02  cluster01-02:e0e   local-only
intercluster01
      Failover Targets:  cluster01-02:e0e,
                           cluster01-02:e0f
```

= Configure intercluster LIFs in custom IPspaces
:icons: font
:relative_path: ./peering/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can configure intercluster LIFs in custom IPspaces. Doing so allows you to isolate replication traffic in multitenant environments.

When you create a custom IPspace, the system creates a system storage virtual machine (SVM) to serve as a container for the system objects in that IPspace. You can use the new SVM as the container for any intercluster LIFs in the new IPspace. The new SVM has the same name as the custom IPspace.

Steps

1. List the ports in the cluster:

```
network port show
```

For complete command syntax, see the man page.

The following example shows the network ports in cluster01:

Node	Port	IPspace	Broadcast	Domain	Link	MTU	Speed (Mbps)
Admin/Oper							

cluster01-01							
	e0a	Cluster	Cluster		up	1500	
auto/1000							
	e0b	Cluster	Cluster		up	1500	
auto/1000							
	e0c	Default	Default		up	1500	
auto/1000							
	e0d	Default	Default		up	1500	
auto/1000							
	e0e	Default	Default		up	1500	
auto/1000							
	e0f	Default	Default		up	1500	
auto/1000							
cluster01-02							
	e0a	Cluster	Cluster		up	1500	
auto/1000							
	e0b	Cluster	Cluster		up	1500	
auto/1000							
	e0c	Default	Default		up	1500	
auto/1000							
	e0d	Default	Default		up	1500	
auto/1000							
	e0e	Default	Default		up	1500	
auto/1000							
	e0f	Default	Default		up	1500	
auto/1000							

2. Create custom IPspaces on the cluster:

```
network ipspace create -ipspace ipspace
```

The following example creates the custom IPspace ipspace-IC1:

```
cluster01::> network ipspace create -ipspace ipspace-IC1
```

3. Determine which ports are available to dedicate to intercluster communication:

```
network interface show -fields home-port,curr-port
```

For complete command syntax, see the man page.

The following example shows that ports e0e and e0f have not been assigned LIFs:

```
cluster01::> network interface show -fields home-port,curr-port
vserver lif          home-port curr-port
-----
Cluster cluster01_clus1    e0a      e0a
Cluster cluster01_clus2    e0b      e0b
Cluster cluster02_clus1    e0a      e0a
Cluster cluster02_clus2    e0b      e0b
cluster01
    cluster_mgmt        e0c      e0c
cluster01
    cluster01-01_mgmt1   e0c      e0c
cluster01
    cluster01-02_mgmt1   e0c      e0c
```

4. Remove the available ports from the default broadcast domain:

```
network port broadcast-domain remove-ports -broadcast-domain Default -ports
ports
```

A port cannot be in more than one broadcast domain at a time. For complete command syntax, see the man page.

The following example removes ports e0e and e0f from the default broadcast domain:

```
cluster01::> network port broadcast-domain remove-ports -broadcast
-domain Default -ports
cluster01-01:e0e,cluster01-01:e0f,cluster01-02:e0e,cluster01-02:e0f
```

5. Verify that the ports have been removed from the default broadcast domain:

```
network port show
```

For complete command syntax, see the man page.

The following example shows that ports e0e and e0f have been removed from the default broadcast domain:

Node	Port	IPspace	Broadcast Domain	Link	MTU	Speed (Mbps)	Admin/Oper
<hr/>							
cluster01-01	e0a	Cluster	Cluster	up	9000	auto/1000	
	e0b	Cluster	Cluster	up	9000	auto/1000	
	e0c	Default	Default	up	1500	auto/1000	
	e0d	Default	Default	up	1500	auto/1000	
	e0e	Default	-	up	1500	auto/1000	
	e0f	Default	-	up	1500	auto/1000	
	e0g	Default	Default	up	1500	auto/1000	
cluster01-02	e0a	Cluster	Cluster	up	9000	auto/1000	
	e0b	Cluster	Cluster	up	9000	auto/1000	
	e0c	Default	Default	up	1500	auto/1000	
	e0d	Default	Default	up	1500	auto/1000	
	e0e	Default	-	up	1500	auto/1000	
	e0f	Default	-	up	1500	auto/1000	
	e0g	Default	Default	up	1500	auto/1000	

6. Create a broadcast domain in the custom IPspace:

```
network port broadcast-domain create -ipspace ipspace -broadcast-domain
broadcast_domain -mtu MTU -ports ports
```

The following example creates the broadcast domain `ipspace-IC1-bd` in the IPspace `ipspace-IC1`:

```
cluster01::> network port broadcast-domain create -ipspace ipspace-
IC1 -broadcast-domain
ipspace-IC1-bd -mtu 1500 -ports cluster01-01:e0e,cluster01-01:e0f,
cluster01-02:e0e,cluster01-02:e0f
```

7. Verify that the broadcast domain was created:

```
network port broadcast-domain show
```

For complete command syntax, see the man page.

```

cluster01::> network port broadcast-domain show
IPspace Broadcast
Name      Domain Name      MTU    Port List          Update
Details
----- -----

                           cluster01-01:e0e      complete
                           cluster01-01:e0f      complete
                           cluster01-02:e0e      complete
                           cluster01-02:e0f      complete

```

8. Create intercluster LIFs on the system SVM and assign them to the broadcast domain:

Option	Description
In ONTAP 9.6 and later:	<pre>network interface create -vserver system_SVM -lif <i>LIF_name</i> -service -policy default-intercluster -home -node <i>node</i> -home-port <i>port</i> -address <i>port_IP</i> -netmask <i>netmask</i></pre>
In ONTAP 9.5 and earlier:	<pre>network interface create -vserver system_SVM -lif <i>LIF_name</i> -role intercluster -home-node <i>node</i> -home -port <i>port</i> -address <i>port_IP</i> -netmask <i>netmask</i></pre>

The LIF is created in the broadcast domain that the home port is assigned to. The broadcast domain has a default failover group with the same name as the broadcast domain. For complete command

syntax, see the man page.

The following example creates intercluster LIFs `cluster01_icl01` and `cluster01_icl02` in the broadcast domain `ipspace-IC1-bd`:

```
cluster01::> network interface create -vserver ipspace-IC1 -lif
cluster01_icl01 -service-
policy default-intercluster -home-node cluster01-01 -home-port e0e
-address 192.168.1.201
-netmask 255.255.255.0

cluster01::> network interface create -vserver ipspace-IC1 -lif
cluster01_icl02 -service-
policy default-intercluster -home-node cluster01-02 -home-port e0e
-address 192.168.1.202
-netmask 255.255.255.0
```

9. Verify that the intercluster LIFs were created:

Option	Description
In ONTAP 9.6 and later:	<code>network interface show -service-policy default-intercluster</code>
In ONTAP 9.5 and earlier:	<code>network interface show -role intercluster</code>

For complete command syntax, see the man page.

```
cluster01::> network interface show -service-policy default-
intercluster
          Logical      Status      Network        Current
Current Is
Vserver     Interface   Admin/Oper Address/Mask       Node
Port       Home
-----
-----
ipspace-IC1
          cluster01_icl01
                      up/up      192.168.1.201/24    cluster01-01
e0e        true
          cluster01_icl02
                      up/up      192.168.1.202/24    cluster01-02
e0f        true
```

10. Verify that the intercluster LIFs are redundant:

Option	Description
In ONTAP 9.6 and later:	<code>network interface show -service-policy default-intercluster -failover</code>
In ONTAP 9.5 and earlier:	<code>network interface show -role intercluster -failover</code>

For complete command syntax, see the man page.

The following example shows that the intercluster LIFs `cluster01_icl01` and `cluster01_icl02` on the SVM `e0e` port fail over to the `e0f` port:

```
cluster01::> network interface show -service-policy default-
intercluster -failover
      Logical          Home          Failover
      Failover
Vserver  Interface       Node:Port        Policy      Group
-----  -----
-----  -----
  ipspace-IC1
      cluster01_icl01  cluster01-01:e0e    local-only
  intercluster01
                      Failover Targets:  cluster01-01:e0e,
                                         cluster01-01:e0f
      cluster01_icl02  cluster01-02:e0e    local-only
  intercluster01
                      Failover Targets:  cluster01-02:e0e,
                                         cluster01-02:e0f
```

= Configure peer relationships

= Create a cluster peer relationship

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can use the `cluster peer create` command to create a peer relationship between a local and remote cluster. After the peer relationship has been created, you can run `cluster peer create` on the remote cluster to authenticate it to the local cluster.

Before you begin

- You must have created intercluster LIFs on every node in the clusters that are being peered.
- The clusters must be running ONTAP 9.3 or later. (If the clusters are running ONTAP 9.2 or earlier, refer to the procedures in [this archived document](#).)

Steps

1. On the destination cluster, create a peer relationship with the source cluster:

```
cluster peer create -generate-passphrase -offer-expiration MM/DD/YYYY
HH:MM:SS|1...7days|1...168hours -peer-addrs peer_LIF_IPs -initial-allowed
-vserver-peers svm_name,...|* -ipspace ipspace
```

If you specify both `-generate-passphrase` and `-peer-addrs`, only the cluster whose intercluster LIFs are specified in `-peer-addrs` can use the generated password.

You can ignore the `-ipspace` option if you are not using a custom IPspace. For complete command syntax, see the man page.

If you are creating the peering relationship in ONTAP 9.6 or later and you do not want cross-cluster peering communications to be encrypted, you must use the `-encryption-protocol-proposed none` option to disable encryption.

The following example creates a cluster peer relationship with an unspecified remote cluster, and pre-authorizes peer relationships with SVMs `vs1` and `vs2` on the local cluster:

```
cluster02::> cluster peer create -generate-passphrase -offer
-expiration 2days -initial-allowed-vserver-peers vs1,vs2

Passphrase: UCa+6lRVICXeL/gq1WrK7ShR
Expiration Time: 6/7/2017 08:16:10 EST
Initial Allowed Vserver Peers: vs1,vs2
Intercluster LIF IP: 192.140.112.101
Peer Cluster Name: Clus_7ShR (temporary generated)
```

Warning: make a note of the passphrase - it cannot be displayed again.

The following example creates a cluster peer relationship with the remote cluster at intercluster LIF IP addresses `192.140.112.103` and `192.140.112.104`, and pre-authorizes a peer relationship with any SVM on the local cluster:

```
cluster02::> cluster peer create -generate-passphrase -peer-addrs  
192.140.112.103,192.140.112.104 -offer-expiration 2days -initial  
-allowed-vserver-peers *
```

```
Passphrase: UCa+6lRVICXeL/gq1WrK7ShR  
Expiration Time: 6/7/2017 08:16:10 EST  
Initial Allowed Vserver Peers: vs1,vs2  
Intercluster LIF IP: 192.140.112.101,192.140.112.102  
Peer Cluster Name: Clus_7ShR (temporary generated)
```

Warning: make a note of the passphrase - it cannot be displayed again.

The following example creates a cluster peer relationship with an unspecified remote cluster, and pre-authorizes peer relationships with SVMs vs1 and vs2 on the local cluster:

```
cluster02::> cluster peer create -generate-passphrase -offer  
-expiration 2days -initial-allowed-vserver-peers vs1,vs2
```

```
Passphrase: UCa+6lRVICXeL/gq1WrK7ShR  
Expiration Time: 6/7/2017 08:16:10 EST  
Initial Allowed Vserver Peers: vs1,vs2  
Intercluster LIF IP: 192.140.112.101  
Peer Cluster Name: Clus_7ShR (temporary generated)
```

Warning: make a note of the passphrase - it cannot be displayed again.

2. On source cluster, authenticate the source cluster to the destination cluster:

```
cluster peer create -peer-addrs peer_LIF_IPs -ipspace ipspace
```

For complete command syntax, see the man page.

The following example authenticates the local cluster to the remote cluster at intercluster LIF IP addresses 192.140.112.101 and 192.140.112.102:

```
cluster01::> cluster peer create -peer-addrs  
192.140.112.101,192.140.112.102
```

Notice: Use a generated passphrase or choose a passphrase of 8 or more characters.

To ensure the authenticity of the peering relationship, use a phrase or sequence of characters that would be hard to guess.

Enter the passphrase:

Confirm the passphrase:

Clusters cluster02 and cluster01 are peered.

Enter the passphrase for the peer relationship when prompted.

3. Verify that the cluster peer relationship was created:

```
cluster peer show -instance
```

```
cluster01::> cluster peer show -instance

                  Peer Cluster Name: cluster02
                  Remote Intercluster Addresses: 192.140.112.101,
192.140.112.102
                  Availability of the Remote Cluster: Available
                  Remote Cluster Name: cluster2
                  Active IP Addresses: 192.140.112.101,
192.140.112.102
                  Cluster Serial Number: 1-80-123456
                  Address Family of Relationship: ipv4
                  Authentication Status Administrative: no-authentication
                  Authentication Status Operational: absent
                  Last Update Time: 02/05 21:05:41
                  IPspace for the Relationship: Default
```

4. Check the connectivity and status of the nodes in the peer relationship:

```
cluster peer health show
```

```

cluster01::> cluster peer health show
Node          cluster-Name           Node-Name
              Ping-Status          RDB-Health Cluster-Health
Avail...
-----

= Create an intercluster SVM peer relationship

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use the `vserver peer create` command to create a peer relationship between SVMs on local and remote clusters.

Before you begin

- The source and destination clusters must be peered.
- The clusters must be running ONTAP 9.3. (If the clusters are running ONTAP 9.2 or earlier, refer to the procedures in [this archived document](#).)

- You must have "pre-authorized" peer relationships for the SVMs on the remote cluster.

For more information, see [Creating a cluster peer relationship](#).

About this task

Previous releases of ONTAP let you authorize a peer relationship for only one SVM at a time. You needed to run the `vserver peer accept` command each time you authorized a pending SVM peer relationship.

Beginning with ONTAP 9.3, you can "pre-authorize" peer relationships for multiple SVMs by listing the SVMs in the `-initial-allowed-vserver` option when you create a cluster peer relationship. For more information, see [Creating a cluster peer relationship](#).

Steps

1. On the data protection destination cluster, display the SVMs that are pre-authorized for peering:

```
vserver peer permission show
```

cluster02::> vserver peer permission show		
Peer Cluster	Vserver	Applications
cluster02	vs1,vs2	snapmirror

2. On the data protection source cluster, create a peer relationship to a pre-authorized SVM on the data protection destination cluster:

```
vserver peer create -vserver local_SVM -peer-vserver remote_SVM
```

For complete command syntax, see the man page.

The following example creates a peer relationship between the local SVM `pvs1` and the pre-authorized remote SVM `vs1`:

```
cluster01::> vserver peer create -vserver pvs1 -peer-vserver vs1
```

3. Verify the SVM peer relationship:

```
vserver peer show
```

```

cluster01::> vserver peer show
      Peer          Peer          Peering
  Remote
  Vserver    Vserver    State    Peer Cluster   Applications
  Vserver
  -----
  -----
  pvs1        vs1        peered   cluster02   snapmirror
  vs1

```

= Add an intercluster SVM peer relationship

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

If you create an SVM after configuring a cluster peer relationship, you will need to add a peer relationship for the SVM manually. You can use the `vserver peer create` command to create a peer relationship between SVMs. After the peer relationship has been created, you can run `vserver peer accept` on the remote cluster to authorize the peer relationship.

Before you begin

The source and destination clusters must be peered.

About this task

You can create a peer relationships between SVMs in the same cluster for local data backup. For more information, see the `vserver peer create` man page.

Administrators occasionally use the `vserver peer reject` command to reject a proposed SVM peer relationship. If the relationship between SVMs is in the rejected state, you must delete the relationship before you can create a new one. For more information, see the `vserver peer delete` man page.

Steps

1. On the data protection source cluster, create a peer relationship with an SVM on the data protection destination cluster:

```
vserver peer create -vserver local_SVM -peer-vserver remote_SVM
-applications snapmirror|file-copy|lun-copy -peer-cluster remote_cluster
```

The following example creates a peer relationship between the local SVM `pvs1` and the remote SVM `vs1`

```

cluster01::> vserver peer create -vserver pvs1 -peer-vserver vs1
-applications snapmirror -peer-cluster cluster02

```

If the local and remote SVMs have the same names, you must use a *local name* to create the SVM

peer relationship:

```
cluster01::> vserver peer create -vserver vs1 -peer-vserver  
vs1 -applications snapmirror -peer-cluster cluster01  
-local-name cluster1vs1LocallyUniqueName
```

2. On the data protection source cluster, verify that the peer relationship has been initiated:

```
vserver peer show-all
```

For complete command syntax, see the man page.

The following example shows that the peer relationship between SVM_{pvs1} and SVM_{vs1} has been initiated:

```
cluster01::> vserver peer show-all  
          Peer          Peer          Peering  
Vserver    Vserver    State     Peer Cluster  Applications  
-----  -----  -----  -----  
pvs1      vs1       initiated   Cluster02    snapmirror
```

3. On the data protection destination cluster, display the pending SVM peer relationship:

```
vserver peer show
```

For complete command syntax, see the man page.

The following example lists the pending peer relationships for cluster02:

```
cluster02::> vserver peer show  
          Peer          Peer  
Vserver    Vserver    State  
-----  -----  
vs1       pvs1       pending
```

4. On the data protection destination cluster, authorize the pending peer relationship:

```
vserver peer accept -vserver local_SVM -peer-vserver remote_SVM
```

For complete command syntax, see the man page.

The following example authorizes the peer relationship between the local SVM vs1 and the remote SVM pvs1:

```
cluster02::> vserver peer accept -vserver vs1 -peer-vserver pvs1
```

5. Verify the SVM peer relationship:

```
vserver peer show
```

```
cluster01::> vserver peer show
      Peer          Peer          Peering
  Remote
  Vserver    Vserver    State    Peer Cluster   Applications
  Vserver
  -----
  -----
  pvs1        vs1       peered   cluster02     snapmirror
  vs1
```

= Enable cluster peering encryption on an existing peer relationship

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

Beginning with ONTAP 9.6, cluster peering encryption is enabled by default on all newly created cluster peering relationships. Cluster peering encryption uses a pre-shared key (PSK) and the Transport Security Layer (TLS) to secure cross-cluster peering communications. This adds an additional layer of security between the peered clusters.

About this task

If you are upgrading peered clusters to ONTAP 9.6 or later, and the peering relationship was created in ONTAP 9.5 or earlier, cluster peering encryption must be enabled manually after upgrading. Both clusters in the peering relationship must be running ONTAP 9.6 or later in order to enable cluster peering encryption.

Steps

1. On the destination cluster, enable encryption for communications with the source cluster:

```
cluster peer modify source_cluster -auth-status-admin use-authentication
-encryption-protocol-proposed tls-psk
```

2. When prompted enter a passphrase.

3. On the data protection source cluster, enable encryption for communication with the data protection destination cluster:

```
cluster peer modify data_protection_destination_cluster -auth-status-admin
use-authentication -encryption-protocol-proposed tls-psk
```

- When prompted, enter the same passphrase entered on the destination cluster.

= Remove cluster peering encryption from an existing peer relationship

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

By default, cluster peering encryption is enabled on all peer relationships created in ONTAP 9.6 or later. If you do not want to use encryption for cross-cluster peering communications, you can disable it.

Steps

- On the destination cluster, modify communications with the source cluster to discontinue use of cluster peering encryption :

- To remove encryption, but maintain authentication enter:

```
cluster peer modify source_cluster -auth-status-admin use-authentication  
-encryption none
```

- To remove encryption and authentication, enter:

```
cluster peer modify source_cluster -auth-status no-authentication
```

- When prompted enter a passphrase.

- On the source cluster, disable encryption for communication with the destination cluster:

- To remove encryption, but maintain authentication enter:

```
cluster peer modify destination_cluster -auth-status-admin use-  
authentication -encrypt none
```

- To remove encryption and authentication, enter:

```
cluster peer modify destination_cluster -auth-status no-authentication
```

- When prompted, enter the same passphrase entered on the destination cluster.

= Where to find additional information

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use CLI commands to manage Snapshot copies on a local ONTAP system and to replicate Snapshot copies to a remote system using SnapMirror. You can replicate Snapshot copies for disaster recovery or long-term retention.

Use these procedures under the following circumstances:

- You want to understand the range of ONTAP backup and recovery capabilities.
- You want to use the command-line interface (CLI), not System Manager, an automated scripting tool, or [SnapCenter Software](#).
- You have already created peer relationships between the source and destination clusters and the source and destination SVMs.

[Cluster and SVM peering](#)

- You are backing up volumes or SVMs from AFF or FAS storage systems to AFF or FAS storage systems.
 - If you are replicating Element volumes to ONTAP, or ONTAP LUNs to an Element system, see the NetApp Element software documentation.

[Replication between NetApp element software and ONTAP](#)

- Beginning with ONTAP 9.10.1, you can create data protection relationships between S3 buckets using S3 SnapMirror. For more information, see [S3 SnapMirror overview](#).

- You want to provide data protection using online methods, not tape.

== Other ways to do this in ONTAP

= Manage local Snapshot copies

= Manage local Snapshot copies overview

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source//encryption-at-rest/..../media/

A *Snapshot copy* is a read-only, point-in-time image of a volume. The image consumes minimal storage space and incurs negligible performance overhead because it records only changes to files since the last Snapshot copy.

You can use a Snapshot copy to restore the entire contents of a volume, or to recover individual files or LUNs. Snapshot copies are stored in the directory `.snapshot` on the volume.

In ONTAP 9.3 and earlier, a volume can contain up to 255 Snapshot copies. In ONTAP 9.4 and later, a FlexVol volume can contain up to 1023 Snapshot copies.

Beginning with ONTAP 9.8, FlexGroup volumes can contain 1023 Snapshot copies. For more information, see [Protect FlexGroup volumes using Snapshot copies](#).

= Configure custom Snapshot policies
= Configure custom Snapshot policies overview
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

A *Snapshot policy* defines how the system creates Snapshot copies. The policy specifies when to create Snapshot copies, how many copies to retain, and how to name them. For example, a system might create one Snapshot copy every day at 12:10 a.m., retain the two most recent copies, and name the copies “*daily.timestamp*.”

The default policy for a volume automatically creates Snapshot copies on the following schedule, with the oldest Snapshot copies deleted to make room for newer copies:

- A maximum of six hourly Snapshot copies taken five minutes past the hour.
- A maximum of two daily Snapshot copies taken Monday through Saturday at 10 minutes after midnight.
- A maximum of two weekly Snapshot copies taken every Sunday at 15 minutes after midnight.

Unless you specify a Snapshot policy when you create a volume, the volume inherits the Snapshot policy associated with its containing storage virtual machine (SVM).

= When to configure a custom Snapshot policy
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

If the default Snapshot policy is not appropriate for a volume, you can configure a custom policy that modifies the frequency, retention, and name of Snapshot copies. The schedule will be dictated mainly by the rate of change of the active file system.

You might back up a heavily used file system like a database every hour, while you back up rarely used files once a day. Even for a database, you will typically run a full backup once or twice a day, while backing up transaction logs every hour.

Other factors are the importance of the files to your organization, your Service Level Agreement (SLA), your Recovery Point Objective (RPO), and your Recovery Time Objective (RTO). Generally speaking, you should retain only as many Snapshot copies as necessary.

= Create a Snapshot job schedule
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

A Snapshot policy requires at least one Snapshot copy job schedule. You can use the `job schedule cron create` command to create a job schedule.

About this task

By default, ONTAP forms the names of Snapshot copies by appending a timestamp to the job schedule name.

If you specify values for both day of the month and day of the week, the values are considered independently. For example, a cron schedule with the day specification Friday and the day of the month specification 13 runs every Friday and on the 13th day of each month, not just on every Friday the 13th.

Step

1. Create a job schedule:

```
job schedule cron create -name job_name -month month -dayofweek day_of_week  
-day day_of_month -hour hour -minute minute
```

For `-month`, `-dayofweek`, and `-hour`, you can specify `all` to run the job every month, day of the week, and hour, respectively.

Beginning with ONTAP 9.10.1, you can include the Vserver for your job schedule:

```
job schedule cron create -name job_name -vserver Vserver_name -month month  
-dayofweek day_of_week -day day_of_month -hour hour -minute minute
```

The following example creates a job schedule named `myweekly` that runs on Saturdays at 3:00 a.m.:

```
cluster1::> job schedule cron create -name myweekly -dayofweek  
"Saturday" -hour 3 -minute 0
```

The following example creates a schedule named `myweeklymulti` that specifies multiple days, hours and minutes:

```
job schedule cron create -name myweeklymulti -dayofweek  
"Monday,Wednesday,Sunday" -hour 3,9,12 -minute 0,20,50
```

= Create a Snapshot policy
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

A Snapshot policy specifies when to create Snapshot copies, how many copies to retain, and how to name them. For example, a system might create one Snapshot copy every day at 12:10 a.m., retain the two most recent copies, and name them “`daily.timestamp`.” A Snapshot policy can contain up to five job schedules.

About this task

By default, ONTAP forms the names of Snapshot copies by appending a timestamp to the job schedule name:

```
daily.2017-05-14_0013/
daily.2017-05-15_0012/
hourly.2017-05-15_1006/          hourly.2017-05-15_1106/
                                hourly.2017-05-15_1206/
                                hourly.2017-05-15_1306/
```

You can substitute a prefix for the job schedule name if you prefer.

The `snapmirror-label` option is for SnapMirror replication. For more information, see [Defining a rule for a policy](#).

Step

1. Create a Snapshot policy:

```
volume snapshot policy create -vserver SVM -policy policy_name -enabled
true|false -schedule1 schedule1_name -count1 copies_to_retain -prefix1
snapshot_prefix -snapmirror-label1 snapshot_label ... -schedule1
schedule5_name -count5 copies_to_retain-prefix5 snapshot_prefix -snapmirror
-label5 snapshot_label
```

The following example creates a Snapshot policy named `snap_policy_daily` that runs on a daily schedule. The policy has a maximum of five Snapshot copies, each with the name `daily.timestamp` and the SnapMirror label `daily`:

```
cluster1::> volume snapshot policy create -vserver vs0 -policy
snap_policy_daily -schedule1 daily -count1 5 -snapmirror-label1
daily
```

= Manage the Snapshot copy reserve

= Manage the Snapshot copy reserve overview

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

The *Snapshot copy reserve* sets aside a percentage of disk space for Snapshot copies, five percent by default. Because Snapshot copies use space in the active file system when the Snapshot copy reserve is exhausted, you might want to increase the Snapshot copy reserve as needed. Alternatively, you can autodelete Snapshot copies when the reserve is full.

= When to increase the Snapshot copy reserve

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

In deciding whether to increase the Snapshot reserve, it's important to remember that a Snapshot copy records only changes to files since the last Snapshot copy was made. It consumes disk space only when blocks in the active file system are modified

or deleted.

This means that the rate of change of the file system is the key factor in determining the amount of disk space used by Snapshot copies. No matter how many Snapshot copies you create, they will not consume disk space if the active file system has not changed.

A FlexVol volume containing database transaction logs, for example, might have a Snapshot copy reserve as large as 20% to account for its greater rate of change. Not only will you want to create more Snapshot copies to capture the more frequent updates to the database, you will also want to have a larger Snapshot copy reserve to handle the additional disk space the Snapshot copies consume.

A Snapshot copy consists of pointers to blocks rather than copies of blocks. You can think of a pointer as a “claim” on a block: ONTAP “holds” the block until the Snapshot copy is deleted.

A Snapshot copy consumes disk space only when blocks in the active file system are modified or deleted.

= How deleting protected files can lead to less file space than expected

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/./media/

A Snapshot copy points to a block even after you delete the file that used the block. This explains why an exhausted Snapshot copy reserve might lead to the counter-intuitive result in which deleting an entire file system results in less space being available than the file system occupied.

Consider the following example. Before deleting any files, the `df` command output is as follows:

```

Filesystem      kbytes  used   avail capacity
/vol/vol0/      3000000 3000000 0       100%
/vol/vol0/.snapshot 1000000 500000 500000 50%

```

After deleting the entire file system and making a Snapshot copy of the volume, the `df` command generates the following output:

```

Filesystem      kbytes  used   avail capacity
/vol/vol0/      3000000 2500000 500000 83%
/vol/vol0/.snapshot 1000000 3500000 0       350%

```

As the output shows, the entire 3 GB formerly used by the active file system is now being used by Snapshot copies, in addition to the 0.5 GB used before the deletion.

Because the disk space used by the Snapshot copies now exceeds the Snapshot copy reserve, the overflow of 2.5 GB “spills” into the space reserved for active files, leaving you with 0.5 GB free space for files where you might reasonably have expected 3 GB.

= Monitor Snapshot copy disk consumption
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can monitor Snapshot copy disk consumption using the `df` command. The command displays the amount of free space in the active file system and the Snapshot copy reserve.

Step

1. Display Snapshot copy disk consumption: `df`

The following example shows Snapshot copy disk consumption:

```

cluster1::> df
Filesystem      kbytes  used   avail capacity
/vol/vol0/      3000000 3000000 0       100%
/vol/vol0/.snapshot 1000000 500000 500000 50%

```

= Check available Snapshot copy reserve on a volume
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You might want to check how much Snapshot copy reserve is available on a volume by using the `snapshot-reserve-available` parameter with the `volume show` command.

Step

1. Check the Snapshot copy reserve available on a volume:

```
vol show -vserver SVM -volume volume -fields snapshot-reserve-available
```

For complete command syntax, see the man page.

The following example displays the available Snapshot copy reserve for `vol1`:

```
cluster1::> vol show -vserver vs0 -volume vol1 -fields snapshot-
reserve-available

vserver volume snapshot-reserve-available
-----
vs0      vol1    4.84GB
```

= Modify the Snapshot copy reserve

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You might want to configure a larger Snapshot copy reserve to prevent Snapshot copies from using space reserved for the active file system. You can decrease the Snapshot copy reserve when you no longer need as much space for Snapshot copies.

Step

1. Modify the Snapshot copy reserve:

```
volume modify -vserver SVM -volume volume -percent-snapshot-space
snap_reserve
```

For complete command syntax, see the man page.

The following example sets the Snapshot copy reserve for `vol1` to 10 percent:

```
cluster1::> volume modify -vserver vs0 -volume vol1 -percent
-snapshot-space 10
```

= Autodelete Snapshot copies

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can use the `volume snapshot autodelete modify` command to trigger automatic deletion of Snapshot copies when the Snapshot reserve is exceeded. By

default, the oldest Snapshot copies are deleted first.

About this task

LUN and file clones are deleted when there are no more Snapshot copies to be deleted.

Step

1. Autodelete Snapshot copies:

```
volume snapshot autodelete modify -vserver SVM -volume volume -enabled  
true|false -trigger volume|snap_reserve
```

For complete command syntax, see the man page.

The following example autodeletes Snapshot copies for `vol1` when the Snapshot copy reserve is exhausted:

```
cluster1::> volume snapshot autodelete modify -vserver vs0 -volume  
vol1 -enabled true -trigger snap_reserve
```

= Restore files from Snapshot copies

= Restore a file from a Snapshot copy on an NFS or SMB client

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

A user on an NFS or SMB client can restore a file directly from a Snapshot copy without the intervention of a storage system administrator.

Every directory in the file system contains a subdirectory named `.snapshot` accessible to NFS and SMB users. The `.snapshot` subdirectory contains subdirectories corresponding to the Snapshot copies of the volume:

```
$ ls .snapshot  
daily.2017-05-14_0013/          hourly.2017-05-15_1106/  
daily.2017-05-15_0012/          hourly.2017-05-15_1206/  
hourly.2017-05-15_1006/         hourly.2017-05-15_1306/
```

Each subdirectory contains the files referenced by the Snapshot copy. If users accidentally delete or overwrite a file, they can restore the file to the parent read-write directory by copying the file from the Snapshot subdirectory to the read-write directory:

```

$ ls my.txt
ls: my.txt: No such file or directory
$ ls .snapshot
daily.2017-05-14_0013/          hourly.2017-05-15_1106/
daily.2017-05-15_0012/          hourly.2017-05-15_1206/
hourly.2017-05-15_1006/         hourly.2017-05-15_1306/
$ ls .snapshot/hourly.2017-05-15_1306/my.txt
my.txt
$ cp .snapshot/hourly.2017-05-15_1306/my.txt .
$ ls my.txt
my.txt

```

= Enable and disable NFS and SMB client access to Snapshot copy directory

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

To determine whether the Snapshot copy directory is visible to NFS and SMB clients to restore a file or LUN from a Snapshot copy, you can enable and disable access to the Snapshot copy directory using the **-snapdir-access** option of the **volume modify** command.

Steps

1. Check the Snapshot directory access status:

```
volume show -vserver SVM_name -volume vol_name -fields snapdir-access
```

Example:

```

clus1::> volume show -vserver vs0 -volume vol1 -fields snapdir-
access
vserver volume snapdir-access
-----
vs0      vol1    false

```

2. Enable or disable the Snapshot copy directory access:

```
volume modify -vserver SVM_name -volume vol_name -snapdir-access true|false
```

The following example enables Snapshot copy directory access on vol1:

```

clus1::> volume modify -vserver vs0 -volume vol1 -snapdir-access
true
Volume modify successful on volume vol1 of Vserver vs0.

```

= Restore a single file from a Snapshot copy
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

You can use the `volume snapshot restore-file` command to restore a single file or LUN from a Snapshot copy. You can restore the file to a different location in the parent read-write volume if you do not want to replace an existing file.

About this task

If you are restoring an existing LUN, a LUN clone is created and backed up in the form of a Snapshot copy. During the restore operation, you can read to and write from the LUN.

Files with streams are restored by default.

Steps

1. List the Snapshot copies in a volume:

```
volume snapshot show -vserver SVM -volume volume
```

For complete command syntax, see the man page.

The following example shows the Snapshot copies in `vol1`:

```
clus1::> volume snapshot show -vserver vs1 -volume vol1

Vserver Volume Snapshot          State    Size  Total% Used%
----- ----- -----
vs1   vol1   hourly.2013-01-25_0005  valid   224KB    0%    0%
                  daily.2013-01-25_0010  valid   92KB     0%    0%
                  hourly.2013-01-25_0105  valid   228KB    0%    0%
                  hourly.2013-01-25_0205  valid   236KB    0%    0%
                  hourly.2013-01-25_0305  valid   244KB    0%    0%
                  hourly.2013-01-25_0405  valid   244KB    0%    0%
                  hourly.2013-01-25_0505  valid   244KB    0%    0%
```

7 entries were displayed.

2. Restore a file from a Snapshot copy:

```
volume snapshot restore-file -vserver SVM -volume volume -snapshot snapshot
-path file_path -restore-path destination_path
```

For complete command syntax, see the man page.

The following example restores the file `myfile.txt`:

```
cluster1::> volume snapshot restore-file -vserver vs0 -volume vol1  
-snapshot daily.2013-01-25_0010 -path /myfile.txt
```

= Restore part of a file from a Snapshot copy

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use the `volume snapshot partial-restore-file` command to restore a range of data from a Snapshot copy to a LUN or to an NFS or SMB container file, assuming you know the starting byte offset of the data and the byte count. You might use this command to restore one of the databases on a host that stores multiple databases in the same LUN.

Beginning in ONTAP 9.12.1, partial restore is available for volumes in an SM-BC relationship.

Steps

1. List the Snapshot copies in a volume:

```
volume snapshot show -vserver SVM -volume volume
```

For complete command syntax, see the man page.

The following example shows the Snapshot copies in `vol1`:

```
clus1::> volume snapshot show -vserver vs1 -volume vol1  
  
Vserver Volume Snapshot State Size Total% Used%  
----- ----- -----  
vs1 vol1 hourly.2013-01-25_0005 valid 224KB 0% 0%  
daily.2013-01-25_0010 valid 92KB 0% 0%  
hourly.2013-01-25_0105 valid 228KB 0% 0%  
hourly.2013-01-25_0205 valid 236KB 0% 0%  
hourly.2013-01-25_0305 valid 244KB 0% 0%  
hourly.2013-01-25_0405 valid 244KB 0% 0%  
hourly.2013-01-25_0505 valid 244KB 0% 0%
```

7 entries were displayed.

2. Restore part of a file from a Snapshot copy:

```
volume snapshot partial-restore-file -vserver SVM -volume volume -snapshot  
snapshot -path file_path -start-byte starting_byte -byte-count byte_count
```

The starting byte offset and byte count must be multiples of 4,096.

The following example restores the first 4,096 bytes of the file `myfile.txt`:

```
cluster1::> volume snapshot partial-restore-file -vserver vs0  
-volume vol1 -snapshot daily.2013-01-25_0010 -path /myfile.txt  
-start-byte 0 -byte-count 4096
```

= Restore the contents of a volume from a Snapshot copy

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use the `volume snapshot restore` command to restore the contents of a volume from a Snapshot copy.

About this task

If the volume has SnapMirror relationships, manually replicate all mirror copies of the volume immediately after you restore from a Snapshot copy. Not doing so can result in unusable mirror copies that must be deleted and recreated.

1. List the Snapshot copies in a volume:

```
volume snapshot show -vserver SVM -volume volume
```

The following example shows the Snapshot copies in `vol1`:

```
clus1::> volume snapshot show -vserver vs1 -volume vol1
```

Vserver	Volume	Snapshot	State	Size	Total%	Used%
vs1	vol1	hourly.2013-01-25_0005	valid	224KB	0%	0%
		daily.2013-01-25_0010	valid	92KB	0%	0%
		hourly.2013-01-25_0105	valid	228KB	0%	0%
		hourly.2013-01-25_0205	valid	236KB	0%	0%
		hourly.2013-01-25_0305	valid	244KB	0%	0%
		hourly.2013-01-25_0405	valid	244KB	0%	0%
		hourly.2013-01-25_0505	valid	244KB	0%	0%

7 entries were displayed.

2. Restore the contents of a volume from a Snapshot copy:

```
volume snapshot restore -vserver SVM -volume volume -snapshot snapshot
```

The following example restores the contents of `vol1`:

```
cluster1::> volume snapshot restore -vserver vs0 -volume vol1  
-snapshot daily.2013-01-25_0010
```

= SnapMirror volume replication

= Asynchronous SnapMirror disaster recovery basics

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/./media/

SnapMirror is disaster recovery technology, designed for failover from primary storage to secondary storage at a geographically remote site. As its name implies, SnapMirror creates a replica, or *mirror*, of your working data in secondary storage from which you can continue to serve data in the event of a catastrophe at the primary site.

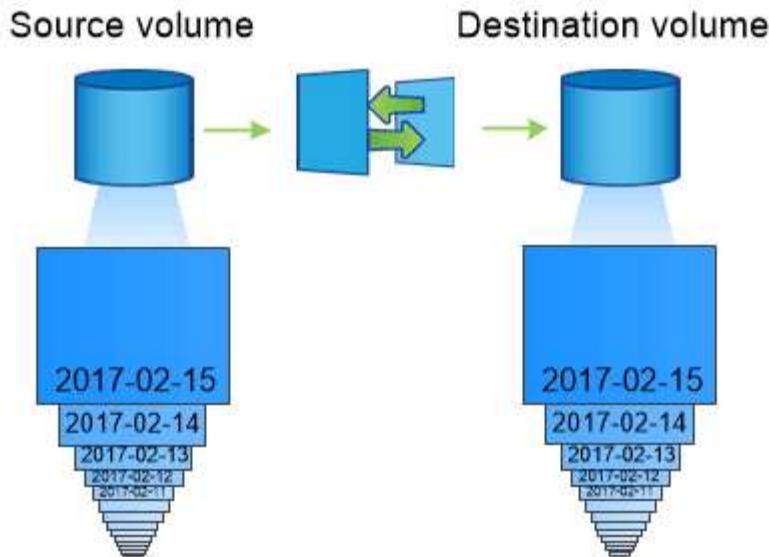

If the primary site is still available to serve data, you can simply transfer any needed data back to it, and not serve clients from the mirror at all. As the failover use case implies, the controllers on the secondary system should be equivalent or nearly equivalent to the controllers on the primary system to serve data efficiently from mirrored storage.

== Data protection relationships

Data is mirrored at the volume level. The relationship between the source volume in primary storage and the destination volume in secondary storage is called a *data protection relationship*. The clusters in which the volumes reside and the SVMs that serve data from the volumes must be *peered*. A peer relationship enables clusters and SVMs to exchange data securely.

Cluster and SVM peering

The figure below illustrates SnapMirror data protection relationships.

A SnapMirror data protection relationship typically mirrors the Snapshot copies available on the source volume.

== Scope of data protection relationships

You can create a data protection relationship directly between volumes or between the SVMs that own the volumes. In an *SVM data protection relationship*, all or part of the SVM configuration, from NFS exports and SMB shares to RBAC, is replicated, as well as the data in the volumes that the SVM owns.

You can also use SnapMirror for special data protection applications:

- A *load-sharing mirror* copy of the SVM root volume ensures that data remains accessible in the event of a node outage or failover.
- A data protection relationship between *SnapLock volumes* lets you replicate WORM files to secondary storage.

Archive and compliance using SnapLock technology

- Beginning in ONTAP 9.13.1, you can use asynchronous SnapMirror to protect [consistency groups](#)

== How SnapMirror data protection relationships are initialized

The first time you invoke SnapMirror, it performs a *baseline transfer* from the source volume to the destination volume. The *SnapMirror policy* for the relationship defines the contents of the baseline and any updates.

A baseline transfer under the default SnapMirror policy `MirrorAllSnapshots` involves the following steps:

- Make a Snapshot copy of the source volume.
- Transfer the Snapshot copy and all the data blocks it references to the destination volume.
- Transfer the remaining, less recent Snapshot copies on the source volume to the destination volume for use in case the “active” mirror is corrupted.

== How SnapMirror data protection relationships are updated

Updates are asynchronous, following the schedule you configure. Retention mirrors the Snapshot policy on the source.

At each update under the `MirrorAllSnapshots` policy, SnapMirror creates a Snapshot copy of the source volume and transfers that Snapshot copy and any Snapshot copies that have been made since the last update. In the following output from the `snapmirror policy show` command for the `MirrorAllSnapshots` policy, note the following:

- `Create Snapshot` is “true”, indicating that `MirrorAllSnapshots` creates a Snapshot copy when SnapMirror updates the relationship.
- `MirrorAllSnapshots` has rules “`sm_created`” and “`all_source_snapshots`”, indicating that both the Snapshot copy created by SnapMirror and any Snapshot copies that have been made since the last update are transferred when SnapMirror updates the relationship.

```
cluster_dst::> snapmirror policy show -policy MirrorAllSnapshots
-instance

          Vserver: vs0
          SnapMirror Policy Name: MirrorAllSnapshots
          SnapMirror Policy Type: async-mirror
          Policy Owner: cluster-admin
          Tries Limit: 8
          Transfer Priority: normal
          Ignore accesstime Enabled: false
          Transfer Restartability: always
          Network Compression Enabled: false
          Create Snapshot: true
          Comment: Asynchronous SnapMirror policy for
mirroring all snapshots
          and the latest active file system.

          Total Number of Rules: 2
          Total Keep: 2
          Rules: SnapMirror Label      Keep  Preserve Warn
Schedule Prefix
          -----
          -----
          sm_created           1   false   0
          -
          -
          all_source_snapshots 1   false   0
          -
```

== MirrorLatest policy

The preconfigured `MirrorLatest` policy works exactly the same way as `MirrorAllSnapshots`, except that only the Snapshot copy created by SnapMirror is transferred at initialization and update.

	Rules: SnapMirror Label	Keep	Preserve	Warn
Schedule Prefix	-----	---	-----	-----
-	sm_created	1	false	0

= SnapMirror Synchronous disaster recovery basics

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

:hardbreaks-option:

Beginning with ONTAP 9.5, SnapMirror Synchronous (SM-S) technology is supported on all FAS and AFF platforms that have at least 16 GB of memory and on all ONTAP Select platforms. SnapMirror Synchronous technology is a per-node, licensed feature that provides synchronous data replication at the volume level.

This functionality addresses the regulatory and national mandates for synchronous replication in financial, healthcare, and other regulated industries where zero data loss is required.

The limit on the number of SnapMirror Synchronous replication operations per HA pair depends on the controller model.

The following table lists the number of SnapMirror Synchronous operations that are allowed per HA pair according to platform type and ONTAP release.

Platform	Releases earlier than ONTAP 9.9.1	ONTAP 9.9.1	ONTAP 9.10.1	ONTAP 9.11.1\ONTAP 9.12.1
AFF	80	160	200	400
FAS	40	80	80	80
ONTAP Select	20	40	40	40

== Supported features

ONTAP 9.12.1 supports non-disruptive SnapMirror Synchronous operations (NDO) on AFF/ASA platforms, only. Support for non-disruptive operations enables you to perform many common maintenance tasks without scheduling down time. Operations supported include takeover and giveback, and volume move, provided that a single node is surviving among each of the two clusters.

The following features are supported for SnapMirror Synchronous technology in ONTAP 9.10.1; provided all nodes in the source and destination cluster are running ONTAP 9.10.1:

- NFSv4.2
- NVMe/TCP

In ONTAP 9.5 and later, SnapMirror Synchronous technology supports the NFSv3, FC, and iSCSI protocols over all networks for which the latency does not exceed 10ms.

SnapMirror Synchronous supports source and destination volumes on FabricPool aggregates with a tiering policy of None, Snapshot, or Auto. The destination volume in a FabricPool aggregate cannot be set to All tiering policy.

The following features are supported for SnapMirror Synchronous technology in ONTAP 9.7:

- Replication of application-created Snapshot copies
If a Snapshot copy is tagged with the appropriate label at the time of the `snapshot create` operation, using the CLI or the ONTAP API, SnapMirror Synchronous replicates the Snapshot copies, both user created or those created with external scripts, after quiescing the applications. Scheduled Snapshot copies created using a Snapshot policy are not replicated. For more information about replicating application-created Snapshot copies, see the Knowledge Base article: [How to replicate application created snapshots with SnapMirror Synchronous](#).
- FC-NVMe
- LUN clones and NVMe namespace clones
LUN clones backed by application-created Snapshot copies are also supported.

The following features are supported for SnapMirror Synchronous technology in ONTAP 9.6; provided all nodes in the source and destination cluster are running ONTAP 9.6:

- SVM DR
 - A SnapMirror Synchronous source can also be a SVM DR source, for example, a fan-out configuration with SM-S as one leg and SVM DR as the other.
 - A SnapMirror Synchronous source cannot be an SVM DR destination because SM-S does not support cascading a DP source.
You must release the synchronous relationship before performing an SVM DR flip resync in the destination cluster.
 - A SnapMirror Synchronous destination cannot be an SVM DR source because SVM DR does not support replication of DP volumes.
A flip resync of the synchronous source would result in the SVM DR excluding the DP volume in the destination cluster.
- NFSv4.0 and NFSv4.1
- SMB 2.0 or later
- Mixed protocol access (NFSv3 and SMB)
- Antivirus on the primary volume of the SnapMirror Synchronous relationship
- Hard or soft quotas on the primary volume of the SnapMirror Synchronous relationship
The quota rules are not replicated to the destination; therefore, the quota database is not replicated to the destination.
- FPolicy on the primary volume of the SnapMirror Synchronous relationship
- SnapMirror Synchronous mirror-mirror cascade
The relationship from the destination volume of the SnapMirror Synchronous relationship must be an asynchronous SnapMirror relationship.
- Timestamp parity between source and destination volumes for NAS
If you have upgraded from ONTAP 9.5 to ONTAP 9.6, the timestamp is replicated only for any new and modified files in the source volume. The timestamp of existing files in the source volume is not

synchronized.

- Removal of high metadata operation frequency limitation
- Security for sensitive data in-transit using TLS 1.2 encryption
- Clone autodelete

Beginning in ONTAP 9.13.1, NDMP is supported with SnapMirror Synchronous. Both the source and destination cluster must be running ONTAP 9.13.1 or later to use NDMP with SnapMirror Synchronous. For more information, see [Transfer data using ndmp copy](#).

== Unsupported features

The following features are not supported with Synchronous SnapMirror relationships:

- Tamperproof Snapshot copies
- Consistency groups
- MetroCluster configurations
- SFMoD
- SFCoD
- VVol
- Mixed SAN and NVMe access
LUNs and NVMe namespaces are not supported on the same volume or SVM.
- SnapLock volumes
- FlexGroup volumes
- FlexCache volumes
- SnapRestore
- DP_Optimized (DPO) systems
- Tape backup or restore using dump and SMTape on the destination volume
- Tape based restore to the source volume
- Throughput floor (QoS Min) for source volumes
- In a fan-out configuration, only one relationship can be a SnapMirror Synchronous relationship; all the other relationships from the source volume must be asynchronous SnapMirror relationships.
- Global throttling

== Modes of operation

SnapMirror Synchronous has two modes of operation based on the type of the SnapMirror policy used:

- **Sync mode**

In Sync mode, application I/O operations are sent in parallel to the primary and secondary storage systems. If the write to the secondary storage is not completed for any reason, the application is allowed to continue writing to the primary storage. When the error condition is corrected, SnapMirror Synchronous technology automatically resynchronizes with the secondary storage and resumes replicating from primary storage to secondary storage in Synchronous mode.

In Sync mode, RPO=0 and RTO is very low until a secondary replication failure occurs at which time RPO and RTO become indeterminate, but equal the time to repair the issue that caused secondary replication to fail and for the resync to complete.

- **StrictSync mode**

SnapMirror Synchronous can optionally operate in StrictSync mode. If the write to the secondary storage is not completed for any reason, the application I/O fails, thereby ensuring that the primary and secondary storage are identical. Application I/O to the primary resumes only after the SnapMirror relationship returns to the `InSync` status. If the primary storage fails, application I/O can be resumed on the secondary storage, after failover, with no loss of data.

In StrictSync mode RPO is always zero, and RTO is very low.

== Relationship status

The status of a SnapMirror Synchronous relationship is always in the `InSync` status during normal operation. If the SnapMirror transfer fails for any reason, the destination is not in sync with the source and can go to the `OutofSync` status.

For SnapMirror Synchronous relationships, the system automatically checks the relationship status (`InSync` or `OutofSync`) at a fixed interval. If the relationship status is `OutofSync`, ONTAP automatically triggers the auto resync process to bring back the relationship to the `InSync` status. Auto resync is triggered only if the transfer fails due to any operation, such as unplanned storage failover at source or destination or a network outage. User-initiated operations such as `snapmirror quiesce` and `snapmirror break` do not trigger auto resync.

If the relationship status becomes `OutofSync` for a SnapMirror Synchronous relationship in the StrictSync mode, all I/O operations to the primary volume are stopped. The `OutofSync` state for SnapMirror Synchronous relationship in the Sync mode is not disruptive to the primary and I/O operations are allowed on the primary volume.

[NetApp Technical Report 4733: SnapMirror Synchronous configuration and best practices](#)

= About workloads supported by StrictSync and Sync policies

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

StrictSync and Sync policies support all LUN-based applications with FC, iSCSI, and FC-NVMe protocols, as well as NFSv3 and NFSv4 protocols for enterprise applications such as databases, VMWare, quota, SMB, and so on. Beginning with ONTAP 9.6, SnapMirror Synchronous can be used for enterprise file services such as electronic design automation (EDA), home directories, and software build workloads.

In ONTAP 9.5, for a Sync policy, you need to consider a few important aspects while selecting the NFSv3 or NFSv4 workloads. The amount of data read or write operations by workloads is not a consideration, as Sync policy can handle high read or write IO workloads. In ONTAP 9.5, workloads that have excessive file creation, directory creation, file permission changes, or directory permission changes may not be suitable (these are referred to as high-metadata workloads). A typical example of a high-metadata workload is a DevOps workload in which you create multiple test files, run automation, and delete the files. Another example is parallel build workload that generate multiple temporary files during compilation. The impact of a high rate of write metadata activity is that it can cause synchronization between mirrors to temporarily break which stalls the read and write IOs from the client.

Beginning with ONTAP 9.6, these limitations are removed and SnapMirror Synchronous can be used for enterprise file services workloads that include multiuser environments, such as home directories and software build workloads.

[SnapMirror Synchronous Configuration and Best Practices](#)

= Vault archiving using SnapMirror technology

:icons: font

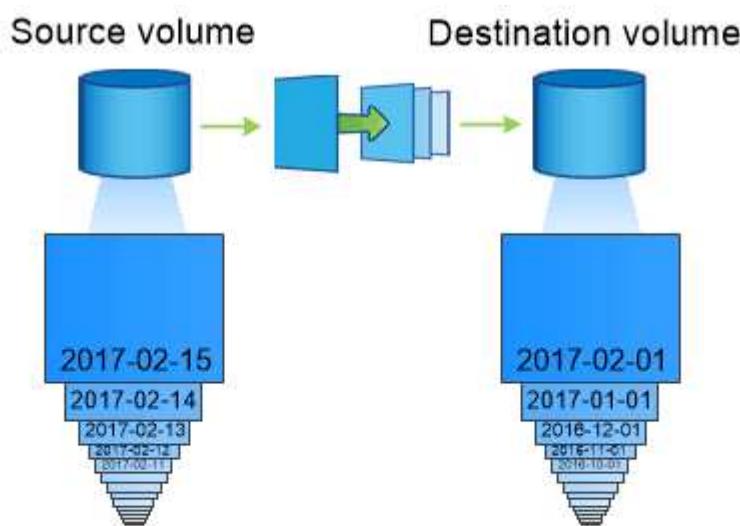

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

SnapMirror vault policies replace SnapVault technology in ONTAP 9.3 and later. You use a SnapMirror vault policy for disk-to-disk Snapshot copy replication for standards compliance and other governance-related purposes. In contrast to a SnapMirror relationship, in which the destination usually contains only the Snapshot copies currently in the source volume, a vault destination typically retains point-in-time Snapshot copies created over a much longer period.

You might want to keep monthly Snapshot copies of your data over a 20-year span, for example, to comply with government accounting regulations for your business. Since there is no requirement to serve data from vault storage, you can use slower, less expensive disks on the destination system.

The figure below illustrates SnapMirror vault data protection relationships.

A SnapVault data protection relationship typically retains point-in-time Snapshot copies created over a longer period than the Snapshot copies on the source volume.

== How vault data protection relationships are initialized

The SnapMirror policy for the relationship defines the contents of the baseline and any updates.

A baseline transfer under the default vault policy XDPDefault makes a Snapshot copy of the source volume, then transfers that copy and the data blocks it references to the destination volume. Unlike SnapMirror relationships, a vault backup does not include older Snapshot copies in the baseline.

== How vault data protection relationships are updated

Updates are asynchronous, following the schedule you configure. The rules you define in the policy for

the relationship identify which new Snapshot copies to include in updates and how many copies to retain. The labels defined in the policy (“monthly,” for example) must match one or more labels defined in the Snapshot policy on the source. Otherwise, replication fails.

At each update under the XDPDefault policy, SnapMirror transfers Snapshot copies that have been made since the last update, provided they have labels matching the labels defined in the policy rules. In the following output from the snapmirror policy show command for the XDPDefault policy, note the following:

- Create Snapshot is “false”, indicating that XDPDefault does not create a Snapshot copy when SnapMirror updates the relationship.
- XDPDefault has rules “daily” and “weekly”, indicating that all Snapshot copies with matching labels on the source are transferred when SnapMirror updates the relationship.

```
cluster_dst::> snapmirror policy show -policy XDPDefault -instance

          Vserver: vs0
      SnapMirror Policy Name: XDPDefault
      SnapMirror Policy Type: vault

          -
          -
          weekly          52  false    0
          -
          -
```

= SnapMirror unified replication basics

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

SnapMirror unified replication allows you to configure disaster recovery and archiving on the same destination volume. When unified replication is appropriate, it offers

benefits in reducing the amount of secondary storage you need, limiting the number of baseline transfers, and decreasing network traffic.

== How unified data protection relationships are initialized

As with SnapMirror, unified data protection performs a baseline transfer the first time you invoke it. The SnapMirror policy for the relationship defines the contents of the baseline and any updates.

A baseline transfer under the default unified data protection policy `MirrorAndVault` makes a Snapshot copy of the source volume, then transfers that copy and the data blocks it references to the destination volume. Like vault archiving, unified data protection does not include older Snapshot copies in the baseline.

== How unified data protection relationships are updated

At each update under the `MirrorAndVault` policy, SnapMirror creates a Snapshot copy of the source volume and transfers that Snapshot copy and any Snapshot copies that have been made since the last update, provided they have labels matching the labels defined in the Snapshot policy rules. In the following output from the `snapmirror policy show` command for the `MirrorAndVault` policy, note the following:

- `Create Snapshot` is “true”, indicating that `MirrorAndVault` creates a Snapshot copy when SnapMirror updates the relationship.
- `MirrorAndVault` has rules “`sm_created`”, “`daily`”, and “`weekly`”, indicating that both the Snapshot copy created by SnapMirror and the Snapshot copies with matching labels on the source are transferred when SnapMirror updates the relationship.

```

cluster_dst:> snapmirror policy show -policy MirrorAndVault -instance

          Vserver: vs0
          SnapMirror Policy Name: MirrorAndVault
          SnapMirror Policy Type: mirror-vault
          Policy Owner: cluster-admin
          Tries Limit: 8
          Transfer Priority: normal
          Ignore accesstime Enabled: false
          Transfer Restartability: always
          Network Compression Enabled: false
          Create Snapshot: true
          Comment: A unified Synchronous SnapMirror and
          SnapVault policy for
                           mirroring the latest file system and
          daily and weekly snapshots.
          Total Number of Rules: 3
          Total Keep: 59
          Rules: SnapMirror Label      Keep  Preserve Warn
Schedule Prefix
          -----
          -----
          sm_created           1   false   0
          -
          -
          daily                7   false   0
          -
          -
          weekly               52  false   0
          -
          -

```

== Unified7year policy

The preconfigured Unified7year policy works exactly the same way as MirrorAndVault, except that a fourth rule transfers monthly Snapshot copies and retains them for seven years.

Schedule Prefix	Rules: SnapMirror Label	Keep	Preserve	Warn
-	sm_created	1	false	0
-	daily	7	false	0
-	weekly	52	false	0
-	monthly	84	false	0
-	-	-	-	-

== Protect against possible data corruption

Unified replication limits the contents of the baseline transfer to the Snapshot copy created by SnapMirror at initialization. At each update, SnapMirror creates another Snapshot copy of the source and transfers that Snapshot copy and any new Snapshot copies that have labels matching the labels defined in the Snapshot policy rules.

You can protect against the possibility that an updated Snapshot copy is corrupted by creating a copy of the last transferred Snapshot copy on the destination. This “local copy” is retained regardless of the retention rules on the source, so that even if the Snapshot originally transferred by SnapMirror is no longer available on the source, a copy of it will be available on the destination.

== When to use unified data replication

You need to weigh the benefit of maintaining a full mirror against the advantages that unified replication offers in reducing the amount of secondary storage, limiting the number of baseline transfers, and decreasing network traffic.

The key factor in determining the appropriateness of unified replication is the rate of change of the active file system. A traditional mirror might be better suited to a volume holding hourly Snapshot copies of database transaction logs, for example.

= XDP replaces DP as the SnapMirror default

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

Beginning with ONTAP 9.3, SnapMirror extended data protection (XDP) mode replaces SnapMirror data protection (DP) mode as the SnapMirror default.

Before upgrading to ONTAP 9.12.1, you must convert existing DP-type relationships to XDP before you can upgrade to ONTAP 9.12.1 and later releases. For more information, see [Convert an existing DP-type relationship to XDP](#).

Until ONTAP 9.3, SnapMirror invoked in DP mode and SnapMirror invoked in XDP mode used different replication engines, with different approaches to version-dependence:

- SnapMirror invoked in DP mode used a *version-dependent* replication engine in which the ONTAP version was required to be the same on primary and secondary storage:

```
cluster_dst::> snapmirror create -type DP -source-path ...
-destination-path ...
```

- SnapMirror invoked in XDP mode used a *version-flexible* replication engine that supported different ONTAP versions on primary and secondary storage:

```
cluster_dst::> snapmirror create -type XDP -source-path ...
-destination-path ...
```

With improvements in performance, the significant benefits of version-flexible SnapMirror outweigh the slight advantage in replication throughput obtained with version-dependent mode. For this reason, beginning with ONTAP 9.3, XDP mode has been made the new default, and any invocations of DP mode on the command line or in new or existing scripts are automatically converted to XDP mode.

Existing relationships are not affected. If a relationship is already of type DP, it will continue to be of type DP. Beginning with ONTAP 9.5, MirrorAndVault is the new default policy when no data protection mode is specified or when XDP mode is specified as the relationship type. The table below shows the behavior you can expect.

If you specify...	The type is...	The default policy (if you do not specify a policy) is...
DP	XDP	MirrorAllSnapshots (SnapMirror DR)
Nothing	XDP	MirrorAndVault (unified replication)
XDP	XDP	MirrorAndVault (unified replication)

As the table shows, the default policies assigned to XDP in different circumstances ensure that the conversion maintains the functional equivalence of the old types. Of course, you can use different policies as needed, including policies for unified replication:

If you specify...	And the policy is...	The result is...
DP	MirrorAllSnapshots	SnapMirror DR
	XDPDefault	SnapVault
	MirrorAndVault	Unified replication

XDP	MirrorAllSnapshots	SnapMirror DR
	XDPDefault	SnapVault
	MirrorAndVault	Unified replication

The only exceptions to conversion are as follows:

- SVM data protection relationships continue to default to DP mode in ONTAP 9.3 and earlier.
Beginning with ONTAP 9.4, SVM data protection relationships default to XDP mode.
- Root volume load-sharing data protection relationships continue to default to DP mode.
- SnapLock data protection relationships continue to default to DP mode in ONTAP 9.4 and earlier.
Beginning with ONTAP 9.5, SnapLock data protection relationships default to XDP mode.
- Explicit invocations of DP continue to default to DP mode if you set the following cluster-wide option:

```
options replication.create_data_protection_rels.enable on
```

This option is ignored if you do not explicitly invoke DP.

= When a destination volume grows automatically
 :icons: font
 :relative_path: ./data-protection/
 :imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

During a data protection mirror transfer, the destination volume grows automatically in size if the source volume has grown, provided there is available space in the aggregate that contains the volume.

This behavior occurs irrespective of any automatic growth setting on the destination. You cannot limit the volume's growth or prevent ONTAP from growing it.

By default, data protection volumes are set to the `grow_shrink` autosize mode, which enables the volume to grow or shrink in response to the amount of used space. The max-autosize for data protection volumes is equal to the maximum FlexVol size and is platform dependent. For example:

- FAS2220, default DP volume max-autosize = 60TB
- FAS6220, default DP volume max-autosize = 70TB
- FAS8200, default DP volume max-autosize = 100TB

For more information, see [NetApp Hardware Universe](#).

= Fan-out and cascade data protection deployments
 :icons: font
 :relative_path: ./data-protection/

You can use a *fan-out* deployment to extend data protection to multiple secondary systems. You can use a *cascade* deployment to extend data protection to tertiary systems.

Both fan-out and cascade deployments support any combination of SnapMirror DR, SnapVault, or unified replication; however, SnapMirror Synchronous relationships (supported beginning with ONTAP 9.5) support only fan-out deployments with one or more asynchronous SnapMirror relationships and do not support cascade deployments. Only one relationship in the fan-out configuration can be a SnapMirror Synchronous relationship, all the other relationships from the source volume must be asynchronous SnapMirror relationships. [SnapMirror Business Continuity](#) (supported beginning with ONTAP 9.8) also supports fan-out configurations.

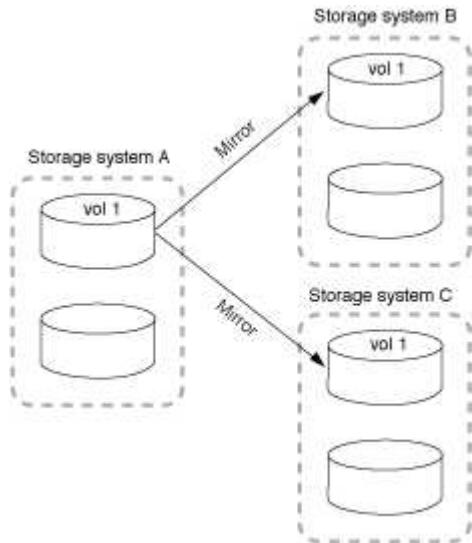

You can use a *fan-in* deployment to create data protection relationships between multiple primary systems and a single secondary system. Each relationship must use a different volume on the secondary system.

You should be aware that volumes that are part of a fan-out or cascade configuration can take longer to resynchronize. It is not uncommon to see the SnapMirror relationship reporting the status "preparing" for an extended time period.

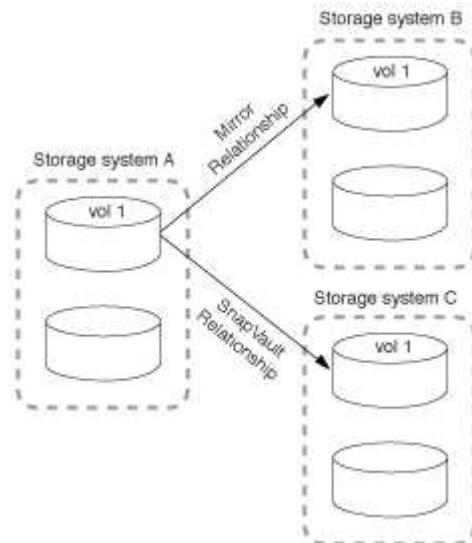

== How fan-out deployments work

SnapMirror supports *multiple-mirrors* and *mirror-vault* fan-out deployments.

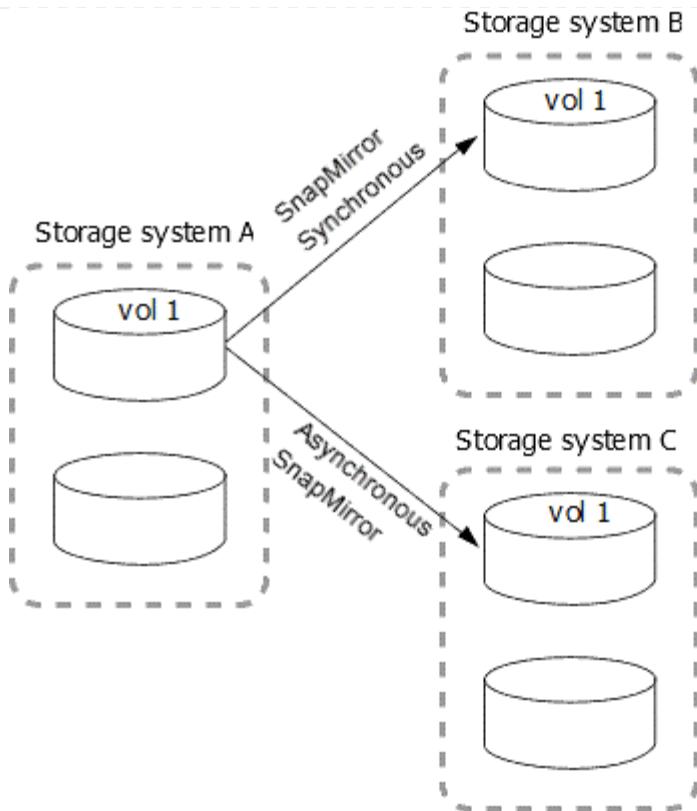

A multiple-mirrors fan-out deployment consists of a source volume that has a mirror relationship to multiple secondary volumes.

A mirror-vault fan-out deployment consists of a source volume that has a mirror relationship to a secondary volume and a SnapVault relationship to a different secondary volume.

Beginning with ONTAP 9.5, you can have fan-out deployments with SnapMirror Synchronous relationships; however, only one relationship in the fan-out configuration can be a SnapMirror Synchronous relationship, all the other relationships from the source volume must be asynchronous SnapMirror relationships.

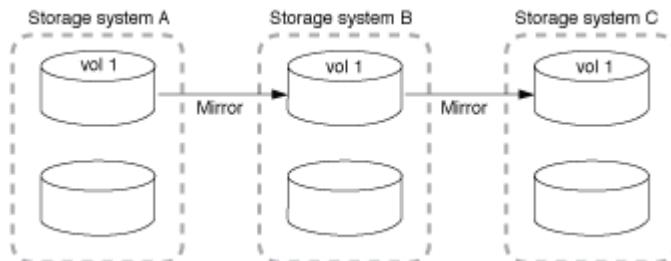

== How cascade deployments work

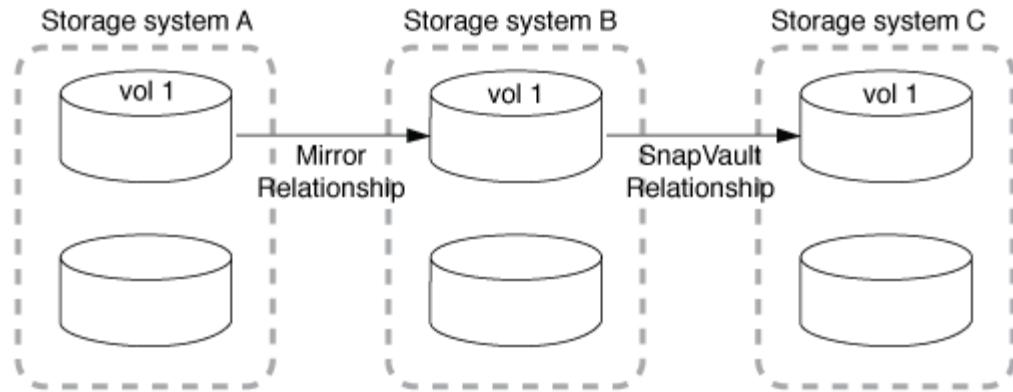

SnapMirror supports *mirror-mirror*, *mirror-vault*, *vault-mirror*, and *vault-vault* cascade deployments.

A mirror-mirror cascade deployment consists of a chain of relationships in which a source volume is mirrored to a secondary volume, and the secondary volume is mirrored to a tertiary volume. If the secondary volume becomes unavailable, you can synchronize the relationship between the primary and tertiary volumes without performing a new baseline transfer.

Beginning with ONTAP 9.6, SnapMirror Synchronous relationships are supported in a mirror-mirror cascade deployment. Only the primary and secondary volumes can be in a SnapMirror Synchronous relationship. The relationship between the secondary volumes and tertiary volumes must be asynchronous.

A mirror-vault cascade deployment consists of a chain of relationships in which a source volume is mirrored to a secondary volume, and the secondary volume is vaulted to a tertiary volume.

Vault-mirror and, beginning with ONTAP 9.2, vault-vault cascade deployments are also supported:

- A vault-mirror cascade deployment consists of a chain of relationships in which a source volume is vaulted to a secondary volume, and the secondary volume is mirrored to a tertiary volume.
- (Beginning with ONTAP 9.2) A vault-vault cascade deployment consists of a chain of relationships in which a source volume is vaulted to a secondary volume, and the secondary volume is vaulted to a tertiary volume.

- [Resume protection in a fan-out configuration with SM-BC](#)

= SnapMirror licensing

= SnapMirror licensing overview

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

Beginning with ONTAP 9.3, licensing has been simplified for replicating between ONTAP instances. In ONTAP 9 releases, the SnapMirror license supports both vault and mirror relationships. Users can now purchase a SnapMirror license to support ONTAP replication for both backup and disaster recovery use cases.

Prior to the ONTAP 9.3 release, two licenses were available to support different replication use cases. A SnapVault license was needed to configure *vault* relationships between ONTAP instances, where the DP instance could retain a higher number of Snapshot copies to support backup use cases where retention times are longer. A SnapMirror license was needed to configure *mirror* relationships between ONTAP instances, where each ONTAP instance would maintain the same number of snapshot copies (that is, a *mirror* image) to support disaster recovery use cases where cluster failovers would be possible. Both SnapMirror and SnapVault licenses can continue to be used and supported for ONTAP 8.x and 9.x releases.

SnapVault licenses continue to function and are supported for both ONTAP 8.x and 9.x releases, but they are no longer being sold. The SnapMirror license continues to be available and can be used in place of SnapVault and can be used for both mirror and vault configurations.

For ONTAP asynchronous replication, beginning with ONTAP 9.3 a single unified replication engine is used to configure extended data protection mode (XDP) policies, where the SnapMirror license can be configured for a mirror policy, a vault policy, or a mirror-vault policy. A SnapMirror license is required on both the source and destination clusters. A SnapVault license is not required if a SnapMirror license is

already installed. The SnapMirror asynchronous perpetual license is included in the Data Protection bundle which you can purchase for your ONTAP clusters. The Data Protection bundle price is based on the raw capacity of the cluster.

Data protection configuration limits are determined using several factors, including your ONTAP version, hardware platform, and the licenses installed. For more information, see [Hardware Universe](#).

== SnapMirror Synchronous license

Beginning with ONTAP 9.5, SnapMirror Synchronous relationships are supported. You require the following licenses for creating a SnapMirror Synchronous relationship:

- The SnapMirror Synchronous license is required on both the source cluster and the destination cluster.

The SnapMirror Synchronous license is enabled with either the Premium bundle or the Data Protection bundle.

If your system was purchased before June 2019 with a Premium or Flash Bundle, you can download a NetApp master key to get the required SnapMirror Synchronous license from the NetApp Support Site: [Master License Keys](#)

- The SnapMirror license is required on both the source cluster and the destination cluster.

== SnapMirror Cloud license

Beginning with ONTAP 9.8, the SnapMirror Cloud license provides asynchronous replication of Snapshot copies from ONTAP instances to object storage endpoints. Replication targets can be configured using both on-premises object stores as well as S3 and S3-compatible public cloud object storage services. SnapMirror Cloud relationships are supported from ONTAP systems to pre-qualified object storage targets. ONTAP 9.8 approved object storage targets include ONTAP S3, StorageGRID, AWS S3 Standard, S3 Standard-IA, and S3 One Zone-IA, Microsoft Azure Blob Premium, Hot and Cool, and GCP Standard and Nearline storage.

SnapMirror Cloud is not available as a standalone license and is available only with purchase of the Hybrid Cloud Bundle. Hybrid Cloud Bundle is a term-based subscription license that is priced based on capacity. Only one license is needed per ONTAP cluster. Capacity is defined as the “used” capacity (not raw capacity) within any volume which is protected by SnapMirror Cloud. Users will purchase this license based on the total used capacity of volumes on the cluster being backed up by SnapMirror Cloud. As of October 2021, the Hybrid Cloud Bundle includes only a SnapMirror Cloud license (previously Hybrid Cloud Bundle included a FabricPool license, which was removed from the bundle effective October 2021). In addition to SnapMirror Cloud, the async SnapMirror license is also required and is available only with the purchase of the Data Protection Bundle.

You require the following licenses for creating a SnapMirror Cloud relationship:

- Both a SnapMirror license (purchased through Data Protection Bundle, or through Premium Bundle) and a SnapMirror Cloud license (purchased through Hybrid Cloud Bundle) are needed for replicating directly to the object store endpoint.
- When configuring a multi-policy replication workflow (for example, Disk-to-Disk-to-Cloud), a SnapMirror license is required on all ONTAP instances, while the SnapMirror Cloud license is only required for the source cluster which is replicating directly to the object storage endpoint.

SnapMirror Cloud is an end user license which can be purchased from NetApp or from an approved NetApp reseller partner. The SnapMirror Cloud license provides end user entitlement but does not enable

asynchronous ONTAP to object storage replication. To invoke ONTAP APIs for SnapMirror Cloud, a unique API key from an authorized application is required. Authorized and licensed applications used to orchestrate SnapMirror Cloud replication include System Manager, and are also available from multiple third-party application providers. These authorized applications will embed the unique API key to invoke ONTAP APIs. A combination of the SnapMirror Cloud end user license and an authorized third-party backup application is required to orchestrate and enable SnapMirror Cloud replication.

Beginning with ONTAP 9.9.1, you can use System Manager for SnapMirror Cloud replication. For more information, see [Back up to the cloud](#).

A list of authorized SnapMirror Cloud third-party applications is published on the NetApp web site.

== Data Protection Optimized (DPO)

Beginning with ONTAP 9.1, new ONTAP data protection features were packaged with the FAS8200 as part of a solution called the Data Protection Bundle. This new hardware and software bundle included a new DP_Optimized (DPO) license that provided unique ONTAP features for secondary workloads. With the introduction of ONTAP 9.3 the DPO license increased the number of volumes per node from 1,000 to 1,500. Also introduced with ONTAP 9.3 were new configurations of the Data Protection Bundle based on configurations of FAS2620.

The DPO license was specifically designed for ONTAP clusters that were to be dedicated as secondary targets for SnapMirror replication. In addition to increasing the maximum volumes per node on the DPO controller, the DPO license also modified controller QoS settings to support greater replication traffic at the expense of application I/O. For this reason, the DPO license should never be installed on a cluster that supports application I/O, as application performance would be impacted. Later, Data Protection Bundles based on the FAS8200 and FAS2620 were offered as a solution and included programmatic free licenses based on the customer environment. When purchasing the solution bundles, free SnapMirror licenses would be provided for select older clusters which replicated to the DPO secondary. While the DPO license is needed on the Data Protection solution cluster, primary clusters from the following platform list would be provided free SnapMirror licenses. Primary clusters not included in this list would require purchase of SnapMirror licenses. The DPO hardware and software bundle was based on both FAS2620 and FAS8200 systems which are both EOA status and no are longer available.

- FAS2200 Series
- FAS3000 Series
- FAS6000 Series
- FAS8000 Series

== Data Protection Optimized (DPO) License

Data Protection hardware and software solution bundles introduced with ONTAP 9.1 and 9.3 were based on FAS8200 and FAS2620 only. As these platforms matured and new platforms were introduced new requests to support ONTAP features for secondary replication use cases increased. As a result, a new standalone DPO license was introduced in November 2018 with the ONTAP 9.5 release.

The standalone DPO license was supported on both FAS and AFF platforms and could be purchased pre-configured with new clusters or added to deployed clusters as a software upgrade in the field. Because these new DPO licenses were not part of a hardware and software solution bundle, they carried a lower price, and free SnapMirror licenses for primary clusters were not provided. Secondary clusters configured with the a la carte DPO license must also purchase a SnapMirror license, and all primary clusters replicating to the DPO secondary cluster must purchase a SnapMirror license.

Additional ONTAP features were delivered with the DPO across multiple ONTAP releases.

Feature	9.3	9.4	9.5	9.6	9.7+
Max vols/node	1500	1500	1500	1500/2500	1500/2500
Max concurrent repl sessions	100	200	200	200	200
Workload bias*	client apps	Apps/SM	SnapMirror	SnapMirror	SnapMirror
Cross volume aggregate deduplication for HDD	No	Yes	Yes	Yes	Yes

- Details about priority for the SnapMirror backoff (workload bias) feature:
- Client: cluster I/O priority is set to client workloads (production apps), not SnapMirror traffic.
- Equality: SnapMirror replication requests have equal priority to I/O for production apps.
- SnapMirror: all SnapMirror I/O requests have higher priority than I/O for production apps.

Table 1: Max FlexVolumes per node across ONTAP releases

	9.3—9.5 Without DPO	9.3—9.5 With DPO	9.6 Without DPO	9.6 With DPO	9.7—9.9.1 Without DPO	9.7—9..9.1 With DPO
FAS2620	1000	1500	1000	1500	1000	1500
FAS2650	1000	1500	1000	1500	1000	1500
FAS2720	1000	1500	1000	1500	1000	1500
FAS2750	1000	1500	1000	1500	1000	1500
A200	1000	1500	1000	1500	1000	1500
A220	1000	1500	1000	1500	1000	1500

A400	1000	1500	1000	2500	2500	2500
FAS8700/9000	1000	1500	1000	2500	1000	2500

A700	1000	1500	1000	2500	2500	2500
A700s	1000	1500	1000	2500	2500	2500
A800	1000	1500	1000	2500	2500	2500

For the latest maximum FlexVol volume support for your configuration, see [Hardware Universe](#).

== Considerations for all new DPO installations

- After it is enabled, the DPO license feature cannot be disabled or undone.
- Installation of the DPO license requires a re-boot of ONTAP or failover to enable.
- The DPO solution is intended for secondary storage workloads; application workload performance on DPO clusters may be impacted
- The DPO license is supported on a select list of NetApp storage platform models.
- DPO features vary by ONTAP release. Refer to the compatibility table for reference.
- New FAS and AFF systems are not qualified with DPO. DPO licenses cannot be purchased for clusters not listed above.

= Install a SnapMirror Cloud license

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source//encryption-at-rest//media/

Beginning with ONTAP 9.8, SnapMirror Cloud provides asynchronous snapshot replication from ONTAP to object storage endpoints. SnapMirror Cloud relationships can only be configured using pre-qualified third-party backup applications. To configure ONTAP to object storage replication, both SnapMirror and SnapMirror Cloud licenses are required on the ONTAP source cluster configured for replication to the object store endpoint.

About this task

The SnapMirror Cloud license is a single-instance cluster-wide license, which means it does not need to be installed on every node in the cluster. It is a term-based license where both term and backup capacity are enforced. In addition to this end user license, SnapMirror Cloud requires an authorized and approved backup application to configure and invoke ONTAP APIs for replication. Both SnapMirror Cloud end user license and authorized app are necessary to utilize SnapMirror Cloud replication.

SnapMirror Cloud licenses are acquired through purchase of the Hybrid Cloud Bundle, which can be purchased with 1 or 3 year terms in 1 TB increments. The Hybrid Cloud Bundle includes a license for SnapMirror Cloud. Each license has a unique serial number. Purchases of the Hybrid Cloud Bundle are based on capacity, where the purchased capacity of the Hybrid Cloud Bundle is applied to the SnapMirror Cloud license.

The SnapMirror Cloud license can be installed on the cluster using the ONTAP command line or System Manager.

Steps

1. Download two NetApp License File (NLF) for SnapMirror Cloud from the NetApp Support Site.

[NetApp Support](#)

2. Use System Manager to upload the SnapMirror Cloud NLF file to the cluster:
 - a. Click **Configuration > Licenses**.
 - b. In the **Cluster Settings** pane, click **Licenses**.
 - c. In the **Packages** window, click **Add**.
 - d. In the **Add License Packages** dialog box, click **Choose Files** to select the NLF you downloaded, and then click **Add** to upload the file to the cluster.

Related information

[NetApp Software License Search](#)

= DPO systems feature enhancements

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

Beginning with ONTAP 9.6, the maximum number of FlexVol volumes supported increases when the DP_Optimized (DPO) license is installed. Beginning with ONTAP 9.4, systems with the DPO license support SnapMirror backoff, cross-volume background deduplication, cross-volume inline deduplication, use of Snapshot blocks as donors, and compaction.

Beginning with ONTAP 9.6, the maximum supported number of FlexVol volumes on secondary or data protection systems has increased, enabling you to scale up to 2,500 FlexVol volumes per node, or up to 5,000 in failover mode. The increase in FlexVol volumes is enabled with the DP_Optimized (DPO) license. A SnapMirror license is still required on both the source and destination nodes.

Beginning with ONTAP 9.4, the following feature enhancements are made to DPO systems:

- SnapMirror backoff: In DPO systems, replication traffic is given the same priority that client workloads are given.

SnapMirror backoff is disabled by default on DPO systems.

- Volume background deduplication and cross-volume background deduplication: Volume background deduplication and cross-volume background deduplication are enabled in DPO systems.

You can run the `storage aggregate efficiency cross-volume-dedupe start -aggregate aggregate_name -scan-old-data true` command to deduplicate the existing data. The best practice is to run the command during off-peak hours to reduce the impact on performance.

- Increased savings by using Snapshot blocks as donors: The data blocks that are not available in the active file system but are trapped in Snapshot copies are used as donors for volume deduplication.

The new data can be deduplicated with the data that was trapped in Snapshot copies, effectively sharing the Snapshot blocks as well. The increased donor space provides more savings, especially when the volume has a large number of Snapshot copies.

- Compaction: Data compaction is enabled by default on DPO volumes.
- = Manage SnapMirror volume replication
- = SnapMirror replication workflow
- :icons: font
- :relative_path: ./data-protection/
- :imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

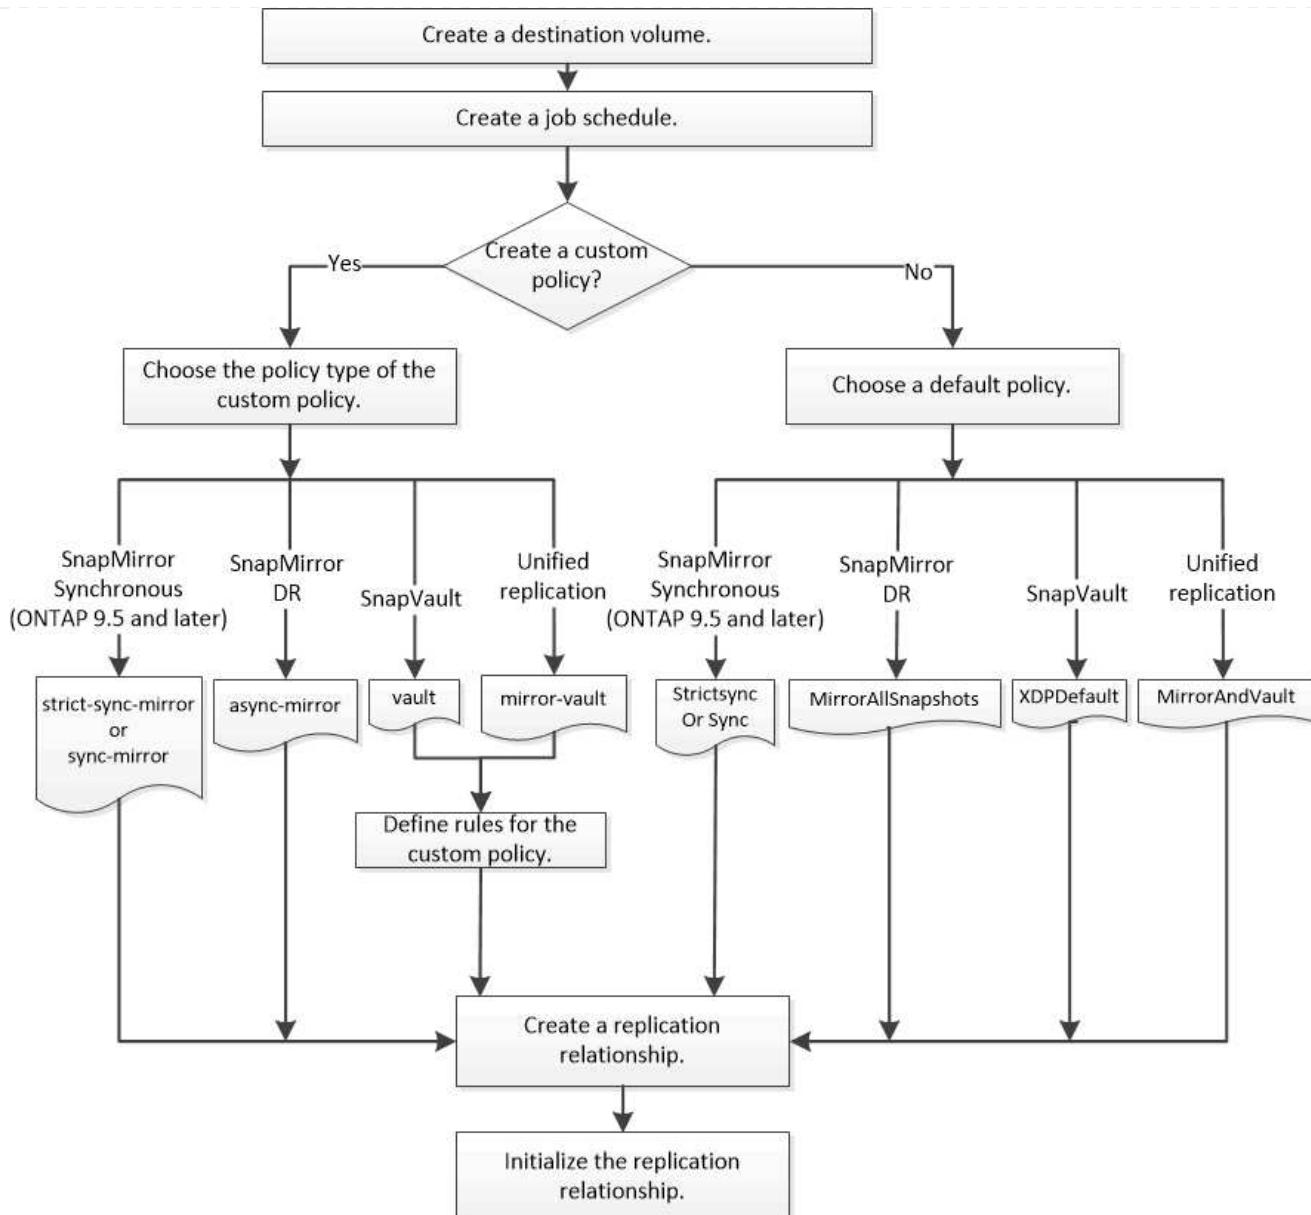

SnapMirror offers three types of data protection relationship: SnapMirror DR, archive (previously known as SnapVault), and unified replication. You can follow the same basic workflow to configure each type of relationship.

Beginning with general availability in ONTAP 9.9.1, SnapMirror Business Continuity (SM-BC) provides Zero Recovery Time Objective (Zero RTO) or Transparent Application Failover (TAF) to enable automatic failover of business-critical applications in SAN environments. SM-BC is supported in a configuration of either two AFF clusters or two All SAN Array (ASA) clusters.

[NetApp Documentation: SnapMirror Business Continuity](#)

For each type of SnapMirror data protection relationship, the workflow is the same: create a destination volume, create a job schedule, specify a policy, create and initialize the relationship.

Beginning with ONTAP 9.3, you can use the `snapmirror protect` command to configure a data protection relationship in a single step. Even if you use `snapmirror protect`, you need to understand each step in the workflow.

= Configure a replication relationship in one step

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/../media/

Beginning with ONTAP 9.3, you can use the `snapmirror protect` command to configure a data protection relationship in a single step. You specify a list of volumes to be replicated, an SVM on the destination cluster, a job schedule, and a SnapMirror policy. `snapmirror protect` does the rest.

What you'll need

- The source and destination clusters and SVMs must be peered.

Cluster and SVM peering

- The language on the destination volume must be the same as the language on the source volume.

About this task

The `snapmirror protect` command chooses an aggregate associated with the specified SVM. If no aggregate is associated with the SVM, it chooses from all the aggregates in the cluster. The choice of aggregate is based on the amount of free space and the number of volumes on the aggregate.

The `snapmirror protect` command then performs the following steps:

- Creates a destination volume with an appropriate type and amount of reserved space for each volume in the list of volumes to be replicated.
- Configures a replication relationship appropriate for the policy you specify.
- Initializes the relationship.

The name of the destination volume is of the form `source_volume_name_dst`. In case of a conflict with an existing name, the command appends a number to the volume name. You can specify a prefix and/or suffix in the command options. The suffix replaces the system-supplied `dst` suffix.

In ONTAP 9.3 and earlier, a destination volume can contain up to 251 Snapshot copies. In ONTAP 9.4 and later, a destination volume can contain up to 1019 Snapshot copies.

Initialization can be time-consuming. `snapmirror protect` does not wait for initialization to complete before the job finishes. For this reason, you should use the `snapmirror show` command rather than the `job show` command to determine when initialization is complete.

Beginning with ONTAP 9.5, SnapMirror Synchronous relationships can be created by using the `snapmirror protect` command.

Step

1. Create and initialize a replication relationship in one step:

```
snapmirror protect -path-list SVM:volume|cluster://SVM/volume, ...
-destination-vserver destination_SVM -policy policy -schedule schedule
-auto-initialize true|false -destination-volume-prefix prefix -destination
-volume-suffix suffix
```

You must run this command from the destination SVM or the destination cluster. The `-auto-initialize` option defaults to “true”.

+

The following example creates and initializes a SnapMirror DR relationship using the default MirrorAllSnapshots policy:

+

```
cluster_dst::> snapmirror protect -path-list svml:volA, svml:volB  
-destination-vserver svm_backup -policy MirrorAllSnapshots -schedule  
replication_daily
```

+

You can use a custom policy if you prefer. For more information, see [Creating a custom replication policy](#).

+

The following example creates and initializes a SnapVault relationship using the default XDPDefault policy:

+

```
cluster_dst::> snapmirror protect -path-list svm1:volA, svm1:volB  
-destination-vserver svm_backup -policy XDPDefault -schedule  
replication_daily
```

+

The following example creates and initializes a unified replication relationship using the default MirrorAndVault policy:

+

```
cluster_dst::> snapmirror protect -path-list svm1:volA, svm1:volB  
-destination-vserver svm_backup -policy MirrorAndVault
```

+

The following example creates and initializes a SnapMirror Synchronous relationship using the default Sync policy:

+

```
cluster_dst::> snapmirror protect -path-list svm1:volA, svm1:volB  
-destination-vserver svm_sync -policy Sync
```

+

For SnapVault and unified replication policies, you might find it useful to define a schedule for creating a copy of the last transferred Snapshot copy on the destination. For more information, see [Defining a schedule for creating a local copy on the destination](#).

After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created. For complete command syntax, see the man page.

= Configure a replication relationship one step at a time

= Create a destination volume

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use the `volume create` command on the destination to create a destination volume. The destination volume should be the same or greater in size than the source volume.

Step

1. Create a destination volume:

```
volume create -vserver SVM -volume volume -aggregate aggregate -type DP  
-size size
```

For complete command syntax, see the man page.

The following example creates a 2-GB destination volume named `volA_dst`:

```
cluster_dst::> volume create -vserver SVM_backup -volume volA_dst  
-aggregate node01_aggr -type DP -size 2GB
```

= Create a replication job schedule

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use the `job schedule cron create` command to create a replication job schedule. The job schedule determines when SnapMirror automatically updates the data protection relationship to which the schedule is assigned.

About this task

You assign a job schedule when you create a data protection relationship. If you do not assign a job schedule, you must update the relationship manually.

Step

1. Create a job schedule:

```
job schedule cron create -name job_name -month month -dayofweek day_of_week  
-day day_of_month -hour hour -minute minute
```

For `-month`, `-dayofweek`, and `-hour`, you can specify `all` to run the job every month, day of the

week, and hour, respectively.

Beginning with ONTAP 9.10.1, you can include the Vserver for your job schedule:

```
job schedule cron create -name job_name -vserver Vserver_name -month month
-dayofweek day_of_week -day day_of_month -hour hour -minute minute
```

The following example creates a job schedule named *my_weekly* that runs on Saturdays at 3:00 a.m.:

```
cluster_dst::> job schedule cron create -name my_weekly -dayofweek
"Saturday" -hour 3 -minute 0
```

= Customize a replication policy

= Create a custom replication policy

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can create a custom replication policy if the default policy for a relationship is not suitable. You might want to compress data in a network transfer, for example, or modify the number of attempts SnapMirror makes to transfer Snapshot copies.

You can use a default or custom policy when you create a replication relationship. For a custom archive (formerly SnapVault) or unified replication policy, you must define one or more *rules* that determine which Snapshot copies are transferred during initialization and update. You might also want to define a schedule for creating local Snapshot copies on the destination.

The *policy type* of the replication policy determines the type of relationship it supports. The table below shows the available policy types.

Policy type	Relationship type
async-mirror	SnapMirror DR
vault	SnapVault
mirror-vault	Unified replication
strict-sync-mirror	SnapMirror Synchronous in the StrictSync mode (supported beginning with ONTAP 9.5)
sync-mirror	SnapMirror Synchronous in the Sync mode (supported beginning with ONTAP 9.5)

When you create a custom replication policy, it is a good idea to model the policy after a default policy.

Step

1. Create a custom replication policy:

```
snapmirror policy create -vserver SVM -policy policy -type async-mirror|vault|mirror-vault|strict-sync-mirror|sync-mirror -comment comment -tries transfer_tries -transfer-priority low|normal -is-network-compression-enabled true|false
```

For complete command syntax, see the man page.

Beginning with ONTAP 9.5, you can specify the schedule for creating a common Snapshot copy schedule for SnapMirror Synchronous relationships by using the `-common-snapshot-schedule` parameter. By default, the common Snapshot copy schedule for SnapMirror Synchronous relationships is one hour. You can specify a value from 30 minutes to two hours for the Snapshot copy schedule for SnapMirror Synchronous relationships.

The following example creates a custom replication policy for SnapMirror DR that enables network compression for data transfers:

```
cluster_dst::> snapmirror policy create -vserver svm1 -policy DR_compressed -type async-mirror -comment "DR with network compression enabled" -is-network-compression-enabled true
```

The following example creates a custom replication policy for SnapVault:

```
cluster_dst::> snapmirror policy create -vserver svm1 -policy my_snapvault -type vault
```

The following example creates a custom replication policy for unified replication:

```
cluster_dst::> snapmirror policy create -vserver svm1 -policy my_unified -type mirror-vault
```

The following example creates a custom replication policy for SnapMirror Synchronous relationship in the StrictSync mode:

```
cluster_dst::> snapmirror policy create -vserver svm1 -policy my_strictsync -type strict-sync-mirror -common-snapshot-schedule my_sync_schedule
```

After you finish

For “vault” and “mirror-vault” policy types, you must define rules that determine which Snapshot copies are transferred during initialization and update.

Use the `snapmirror policy show` command to verify that the SnapMirror policy was created. For complete command syntax, see the man page.

= Define a rule for a policy
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

For custom policies with the “vault” or “mirror-vault” policy type, you must define at least one rule that determines which Snapshot copies are transferred during initialization and update. You can also define rules for default policies with the “vault” or “mirror-vault” policy type.

About this task

Every policy with the “vault” or “mirror-vault” policy type must have a rule that specifies which Snapshot copies to replicate. The rule “bi-monthly”, for example, indicates that only Snapshot copies assigned the SnapMirror label “bi-monthly” should be replicated. You specify the SnapMirror label when you configure the Snapshot policy on the source.

Each policy type is associated with one or more system-defined rules. These rules are automatically assigned to a policy when you specify its policy type. The table below shows the system-defined rules.

System-defined rule	Used in policy types	Result
sm_created	async-mirror, mirror-vault, Sync, StrictSync	A Snapshot copy created by SnapMirror is transferred on initialization and update.
all_source_snapshots	async-mirror	New Snapshot copies on the source are transferred on initialization and update.
daily	vault,mirror-vault	New Snapshot copies on the source with the SnapMirror label “daily” are transferred on initialization and update.
weekly	vault,mirror-vault	New Snapshot copies on the source with the SnapMirror label “weekly” are transferred on initialization and update.
monthly	mirror-vault	New Snapshot copies on the source with the SnapMirror label “monthly” are transferred on initialization and update.

app_consistent	Sync, StrictSync	Snapshot copies with the SnapMirror label “app_consistent” on source are synchronously replicated to the destination. Supported Beginning with ONTAP 9.7.
----------------	------------------	---

Except for the “async-mirror” policy type, you can specify additional rules as needed, for default or custom policies. For example:

- For the default `MirrorAndVault` policy, you might create a rule called “bi-monthly” to match Snapshot copies on the source with the “bi-monthly” SnapMirror label.
- For a custom policy with the “mirror-vault” policy type, you might create a rule called “bi-weekly” to match Snapshot copies on the source with the “bi-weekly” SnapMirror label.

Step

1. Define a rule for a policy:

```
snapmirror policy add-rule -vserver SVM -policy policy_for_rule -snapmirror
-label snapmirror-label -keep retention_count
```

For complete command syntax, see the man page.

The following example adds a rule with the SnapMirror label `bi-monthly` to the default `MirrorAndVault` policy:

```
cluster_dst::> snapmirror policy add-rule -vserver svml -policy
MirrorAndVault -snapmirror-label bi-monthly -keep 6
```

The following example adds a rule with the SnapMirror label `bi-weekly` to the custom `my_snapvault` policy:

```
cluster_dst::> snapmirror policy add-rule -vserver svml -policy
my_snapvault -snapmirror-label bi-weekly -keep 26
```

The following example adds a rule with the SnapMirror label `app_consistent` to the custom `Sync` policy:

```
cluster_dst::> snapmirror policy add-rule -vserver svml -policy Sync
-snapmirror-label app_consistent -keep 1
```

You can then replicate Snapshot copies from the source cluster that match this SnapMirror label:

```
cluster_src::> snapshot create -vserver vs1 -volume vol1 -snapshot  
snapshot1 -snapmirror-label app_consistent
```

= Define a schedule for creating a local copy on the destination

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

For SnapVault and unified replication relationships, you can protect against the possibility that an updated Snapshot copy is corrupted by creating a copy of the last transferred Snapshot copy on the destination. This “local copy” is retained regardless of the retention rules on the source, so that even if the Snapshot originally transferred by SnapMirror is no longer available on the source, a copy of it will be available on the destination.

About this task

You specify the schedule for creating a local copy in the `-schedule` option of the `snapmirror policy add-rule` command.

Step

1. Define a schedule for creating a local copy on the destination:

```
snapmirror policy add-rule -vserver SVM -policy policy_for_rule -snapmirror  
-label snapmirror-label -schedule schedule
```

For complete command syntax, see the man page. For an example of how to create a job schedule, see [Creating a replication job schedule](#).

The following example adds a schedule for creating a local copy to the default `MirrorAndVault` policy:

```
cluster_dst::> snapmirror policy add-rule -vserver svm1 -policy  
MirrorAndVault -snapmirror-label my_monthly -schedule my_monthly
```

The following example adds a schedule for creating a local copy to the custom `my_unified` policy:

```
cluster_dst::> snapmirror policy add-rule -vserver svm1 -policy  
my_unified -snapmirror-label my_monthly -schedule my_monthly
```

= Create a replication relationship

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

The relationship between the source volume in primary storage and the destination

volume in secondary storage is called a *data protection relationship*. You can use the snapmirror create command to create SnapMirror DR, SnapVault, or unified replication data protection relationships.

What you'll need

- The source and destination clusters and SVMs must be peered.

Cluster and SVM peering

- The language on the destination volume must be the same as the language on the source volume.

About this task

Until ONTAP 9.3, SnapMirror invoked in DP mode and SnapMirror invoked in XDP mode used different replication engines, with different approaches to version-dependence:

- SnapMirror invoked in DP mode used a *version-dependent* replication engine in which the ONTAP version was required to be the same on primary and secondary storage:

```
cluster_dst::> snapmirror create -type DP -source-path ...
-destination-path ...
```

- SnapMirror invoked in XDP mode used a *version-flexible* replication engine that supported different ONTAP versions on primary and secondary storage:

```
cluster_dst::> snapmirror create -type XDP -source-path ...
-destination-path ...
```

With improvements in performance, the significant benefits of version-flexible SnapMirror outweigh the slight advantage in replication throughput obtained with version-dependent mode. For this reason, beginning with ONTAP 9.3, XDP mode has been made the new default, and any invocations of DP mode on the command line or in new or existing scripts are automatically converted to XDP mode.

Existing relationships are not affected. If a relationship is already of type DP, it will continue to be of type DP. The table below shows the behavior you can expect.

If you specify...	The type is...	The default policy (if you do not specify a policy) is...
DP	XDP	MirrorAllSnapshots (SnapMirror DR)
Nothing	XDP	MirrorAllSnapshots (SnapMirror DR)
XDP	XDP	XDPDefault (SnapVault)

See also the examples in the procedure below.

The only exceptions to conversion are as follows:

- SVM data protection relationships continue to default to DP mode.

Specify XDP explicitly to obtain XDP mode with the default `MirrorAllSnapshots` policy.

- Load-sharing data protection relationships continue to default to DP mode.
- SnapLock data protection relationships continue to default to DP mode.
- Explicit invocations of DP continue to default to DP mode if you set the following cluster-wide option:

```
options replication.create_data_protection_rels.enable on
```

This option is ignored if you do not explicitly invoke DP.

In ONTAP 9.3 and earlier, a destination volume can contain up to 251 Snapshot copies. In ONTAP 9.4 and later, a destination volume can contain up to 1019 Snapshot copies.

Beginning with ONTAP 9.5, SnapMirror Synchronous relationships are supported.

Step

1. From the destination cluster, create a replication relationship:

```
snapmirror create -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ... -type DP|XDP -schedule
schedule -policy policy
```

For complete command syntax, see the man page.

The `schedule` parameter is not applicable when creating SnapMirror Synchronous relationships.

+

The following example creates a SnapMirror DR relationship using the default MirrorLatest policy:

+

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type XDP -schedule my_daily -policy  
MirrorLatest
```

+

The following example creates a SnapVault relationship using the default XDPDefault policy:

+

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type XDP -schedule my_daily -policy  
XDPDefault
```

+

The following example creates a unified replication relationship using the default MirrorAndVault policy:

+

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type XDP -schedule my_daily -policy  
MirrorAndVault
```

+

The following example creates a unified replication relationship using the custom my_unified policy:

+

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type XDP -schedule my_daily -policy  
my_unified
```

+

The following example creates a SnapMirror Synchronous relationship using the default sync policy:

+

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type XDP -policy Sync
```

+

The following example creates a SnapMirror Synchronous relationship using the default StrictSync policy:

+

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type XDP -policy StrictSync
```

+

The following example creates a SnapMirror DR relationship. With the DP type automatically converted to XDP and with no policy specified, the policy defaults to the MirrorAllSnapshots policy:

+

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type DP -schedule my_daily
```

+

The following example creates a SnapMirror DR relationship. With no type or policy specified, the policy defaults to the MirrorAllSnapshots policy:

+

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -schedule my_daily
```

+

The following example creates a SnapMirror DR relationship. With no policy specified, the policy defaults to the XDPDefault policy:

+

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type XDP -schedule my_daily
```

+

The following example creates a SnapMirror Synchronous relationship with the predefined policy SnapCenterSync:

+

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type XDP -policy SnapCenterSync
```

+

The predefined policy `SnapCenterSync` is of type `Sync`. This policy replicates any Snapshot copy that is created with the `snapmirror-label` of "app_consistent".

After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created. For complete command syntax, see the man page.

== Other ways to do this in ONTAP

To perform these tasks with...	See this content...
The redesigned System Manager (available with ONTAP 9.7 and later)	Configure mirrors and vaults
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume backup using SnapVault overview

= Initialize a replication relationship

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

For all relationship types, initialization performs a *baseline transfer*: it makes a Snapshot copy of the source volume, then transfers that copy and all the data blocks it references to the destination volume. Otherwise, the contents of the transfer depend on the policy.

What you'll need

The source and destination clusters and SVMs must be peered.

[Cluster and SVM peering](#)

About this task

Initialization can be time-consuming. You might want to run the baseline transfer in off-peak hours.

Beginning with ONTAP 9.5, SnapMirror Synchronous relationships are supported.

Step

1. Initialize a replication relationship:

```
snapmirror initialize -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

+

The following example initializes the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

+

```
cluster_dst::> snapmirror initialize -source-path svm1:volA  
-destination-path svm_backup:volA_dst
```

= Example: Configure a vault-vault cascade

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

An example will show in concrete terms how you can configure replication relationships one step at a time. You can use the vault-vault cascade deployment configured in the example to retain more than 251 Snapshot copies labeled “my-weekly”.

What you'll need

- The source and destination clusters and SVMs must be peered.
- You must be running ONTAP 9.2 or later. Vault-vault cascades are not supported in earlier ONTAP releases.

About this task

The example assumes the following:

- You have configured Snapshot copies on the source cluster with the SnapMirror labels “my-daily”, “my-weekly”, and “my-monthly”.
- You have configured destination volumes named “volA” on the secondary and tertiary destination clusters.
- You have configured replication job schedules named “my_snapvault” on the secondary and tertiary destination clusters.

The example shows how to create replication relationships based on two custom policies:

- The “snapvault_secondary” policy retains 7 daily, 52 weekly, and 180 monthly Snapshot copies on the secondary destination cluster.
- The “snapvault_tertiary policy” retains 250 weekly Snapshot copies on the tertiary destination cluster.

Steps

1. On the secondary destination cluster, create the “snapvault_secondary” policy:

```
cluster_secondary::> snapmirror policy create -policy snapvault_secondary  
-type vault -comment "Policy on secondary for vault to vault cascade"  
-vserver svm_secondary
```

2. On the secondary destination cluster, define the “my-daily” rule for the policy:

```
cluster_secondary::> snapmirror policy add-rule -policy snapvault_secondary  
-snapmirror-label my-daily -keep 7 -vserver svm_secondary
```

3. On the secondary destination cluster, define the “my-weekly” rule for the policy:

```
cluster_secondary::> snapmirror policy add-rule -policy snapvault_secondary  
-snapmirror-label my-weekly -keep 52 -vserver svm_secondary
```

4. On the secondary destination cluster, define the “my-monthly” rule for the policy:

```
cluster_secondary::> snapmirror policy add-rule -policy snapvault_secondary  
-snapmirror-label my-monthly -keep 180 -vserver svm_secondary
```

5. On the secondary destination cluster, verify the policy:

```
cluster_secondary::> snapmirror policy show snapvault_secondary -instance
```

```
Vserver: svm_secondary
SnapMirror Policy Name: snapvault_secondary
SnapMirror Policy Type: vault
    Policy Owner: cluster-admin
    Tries Limit: 8
    Transfer Priority: normal
    Ignore accesstime Enabled: false
    Transfer Restartability: always
    Network Compression Enabled: false
        Create Snapshot: false
        Comment: Policy on secondary for vault to vault
cascade
    Total Number of Rules: 3
    Total Keep: 239
        Rules: SnapMirror Label      Keep  Preserve
Warn Schedule Prefix
----- -----
---- ----- -----
                    my-daily           7   false
0  -          -
                    my-weekly          52   false
0  -          -
                    my-monthly         180   false
0  -          -
```

6. On the secondary destination cluster, create the relationship with the source cluster:

```
cluster_secondary::> snapmirror create -source-path svm_primary:volA  
-destination-path svm_secondary:volA -type XDP -schedule my_snapvault  
-policy snapvault_secondary
```

7. On the secondary destination cluster, initialize the relationship with the source cluster:

```
cluster_secondary::> snapmirror initialize -source-path svm_primary:volA  
-destination-path svm_secondary:volA
```

8. On the tertiary destination cluster, create the “snapvault_ternary” policy:

```
cluster_ternary::> snapmirror policy create -policy snapvault_ternary  
-type vault -comment "Policy on tertiary for vault to vault cascade"  
-vserver svm_ternary
```

9. On the tertiary destination cluster, define the “my-weekly” rule for the policy:

```
cluster_ternary::> snapmirror policy add-rule -policy snapvault_ternary  
-snapmirror-label my-weekly -keep 250 -vserver svm_ternary
```

10. On the tertiary destination cluster, verify the policy:

```
cluster_ternary::> snapmirror policy show snapvault_ternary -instance
```

```
Vserver: svm_ternary
SnapMirror Policy Name: snapvault_ternary
SnapMirror Policy Type: vault
    Policy Owner: cluster-admin
    Tries Limit: 8
    Transfer Priority: normal
    Ignore accesstime Enabled: false
    Transfer Restartability: always
    Network Compression Enabled: false
    Create Snapshot: false
    Comment: Policy on tertiary for vault to vault
cascade
    Total Number of Rules: 1
    Total Keep: 250
    Rules: SnapMirror Label      Keep  Preserve
Warn Schedule Prefix
-----
-----
0   -           my-weekly      250  false
```

11. On the tertiary destination cluster, create the relationship with the secondary cluster:

```
cluster_ternary::> snapmirror create -source-path svm_secondary:volA  
-destination-path svm_ternary:volA -type XDP -schedule my_snapvault  
-policy snapvault_ternary
```

12. On the tertiary destination cluster, initialize the relationship with the secondary cluster:

```
cluster_ternary::> snapmirror initialize -source-path svm_secondary:volA  
-destination-path svm_ternary:volA
```

= Convert an existing DP-type relationship to XDP

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

You can easily convert an existing DP-type relationship to XDP to take advantage of version-flexible SnapMirror.

About this task

- If you are upgrading to ONTAP 9.12.1 or later, you must convert DP-type relationships to XDP before upgrading. ONTAP 9.12.1 and later does not support DP-type relationships.
- SnapMirror does not automatically convert existing DP-type relationships to XDP. To convert the relationship, you need to break and delete the existing relationship, create a new XDP relationship, and resync the relationship. For background information, see [XDP replaces DP as the SnapMirror default](#).
- When planning your conversion, you should be aware that background preparation and the data warehousing phase of an XDP SnapMirror relationship can take a long time. It is not uncommon to see the SnapMirror relationship reporting the status "preparing" for an extended time period.

After you convert a SnapMirror relationship type from DP to XDP, space-related settings, such as autosize and space guarantee are no longer replicated to the destination.

Steps

1. From the destination cluster, ensure that the SnapMirror relationship is type DP, that the mirror state is SnapMirrored, the relationship status is Idle, and the relationship is healthy:

```
snapmirror show -destination-path SVM:volume|cluster://SVM/volume
```

The following example shows the output from the `snapmirror show` command:

```
cluster_dst::>snapmirror show -destination-path svm_backup:volA_dst

Source Path: svm1:volA
Destination Path: svm_backup:volA_dst
Relationship Type: DP
SnapMirror Schedule: -
Tries Limit: -
Throttle (KB/sec): unlimited
Mirror State: Snapmirrored
Relationship Status: Idle
Transfer Snapshot: -
Snapshot Progress: -
Total Progress: -
Snapshot Checkpoint: -
Newest Snapshot: snapmirror.10af643c-32d1-11e3-954b-
123478563412_2147484682.2014-06-27_100026
Newest Snapshot Timestamp: 06/27 10:00:55
Exported Snapshot: snapmirror.10af643c-32d1-11e3-954b-
123478563412_2147484682.2014-06-27_100026
Exported Snapshot Timestamp: 06/27 10:00:55
Healthy: true
```

You might find it helpful to retain a copy of the `snapmirror show` command output to keep track existing of the relationship settings.

1. From the source and the destination volumes, ensure that both volumes have a common Snapshot copy:

```
volume snapshot show -vserver SVM -volume volume
```

The following example shows the `volume snapshot show` output for the source and the destination volumes:

```

cluster_src:> volume snapshot show -vserver vsm1 -volume volA

snapmirror.10af643c-32d1-11e3-954b-123478563412_2147484682.2014-06-
27_100026

```

2. To ensure scheduled updates will not run during the conversion, quiesce the existing DP-type relationship:

```
snapmirror quiesce -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

+

The following example quiesces the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

+

```
cluster_dst::> snapmirror quiesce -destination-path svm_backup:volA_dst
```

1. Break the existing DP-type relationship:

```
snapmirror break -destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

+

The following example breaks the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

+

```
cluster_dst::> snapmirror break -destination-path svm_backup:volA_dst
```

1. If automatic deletion of Snapshot copies is enabled on the destination volume, disable it:

```
volume snapshot autodelete modify -vserver SVM -volume volume -enabled false
```

The following example disables Snapshot copy autodelete on the destination volume `volA_dst`:

```
cluster_dst::> volume snapshot autodelete modify -vserver svm_backup -volume volA_dst -enabled false
```

2. Delete the existing DP-type relationship:

```
snapmirror delete -destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

+

The following example deletes the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

+

```
cluster_dst::> snapmirror delete -destination-path svm_backup:volA_dst
```

1. You can use the output you retained from the `snapmirror show` command to create the new XDP-type relationship:

```
snapmirror create -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ... -type XDP -schedule  
schedule -policy policy
```

The new relationship must use the same source and destination volume. For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

+

The following example creates a SnapMirror DR relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup` using the default `MirrorAllSnapshots` policy:

+

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination
-path svm_backup:volA_dst
-type XDP -schedule my_daily -policy MirrorAllSnapshots
```

1. Resync the source and destination volumes:

```
snapmirror resync -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

To improve resync time, you can use the `-quick-resync` option, but you should be aware that storage efficiency savings can be lost. For complete command syntax, see the man page: [SnapMirror resync command](#).

You must run this command from the destination SVM or the destination cluster. Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.

+

The following example resyncs the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

+

```
cluster_dst::> snapmirror resync -source-path svm1:volA -destination
-path svm_backup:volA_dst
```

1. If you disabled automatic deletion of Snapshot copies, reenable it:

```
volume snapshot autodelete modify -vserver SVM -volume volume -enabled true
```

After you finish

1. Use the `snapmirror show` command to verify that the SnapMirror relationship was created. For complete command syntax, see the man page.
2. Once the SnapMirror XDP destination volume begins updating Snapshot copies as defined by the SnapMirror policy, you can use the output of `snapmirror list-destinations` command from the source cluster to display the new SnapMirror XDP relationship.

= Convert the type of a SnapMirror relationship

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

Beginning with ONTAP 9.5, SnapMirror Synchronous is supported. You can convert an asynchronous SnapMirror relationship to a SnapMirror Synchronous relationship or vice versa without performing a baseline transfer.

About this task

You cannot convert an asynchronous SnapMirror relationship to a SnapMirror Synchronous relationship or vice versa by changing the SnapMirror policy

Steps

- **Converting an asynchronous SnapMirror relationship to a SnapMirror Synchronous relationship**

- a. From the destination cluster, delete the asynchronous SnapMirror relationship:

```
snapmirror delete -destination-path SVM:volume
```

```
cluster2::>snapmirror delete -destination-path vs1_dr:vol1
```

- b. From the source cluster, release the SnapMirror relationship without deleting the common Snapshot copies:

```
snapmirror release -relationship-info-only true -destination-path
dest_SVM:dest_volume
```

```
cluster1::>snapmirror release -relationship-info-only true  
-destination-path vs1_dr:vol1
```

- c. From the destination cluster, create a SnapMirror Synchronous relationship:

```
snapmirror create -source-path src_SVM:src_volume -destination-path  
dest_SVM:dest_volume -policy sync-mirror
```

```
cluster2::>snapmirror create -source-path vs1:vol1 -destination  
-path vs1_dr:vol1 -policy sync
```

- d. Resynchronize the SnapMirror Synchronous relationship:

```
snapmirror resync -destination-path dest_SVM:dest_volume
```

```
cluster2::>snapmirror resync -destination-path vs1_dr:vol1
```

- **Converting a SnapMirror Synchronous relationship to an asynchronous SnapMirror relationship**

- a. From the destination cluster, quiesce the existing SnapMirror Synchronous relationship:

```
snapmirror quiesce -destination-path dest_SVM:dest_volume
```

```
cluster2::> snapmirror quiesce -destination-path vs1_dr:vol1
```

- b. From the destination cluster, delete the asynchronous SnapMirror relationship:

```
snapmirror delete -destination-path SVM:volume
```

```
cluster2::>snapmirror delete -destination-path vs1_dr:vol1
```

- c. From the source cluster, release the SnapMirror relationship without deleting the common Snapshot copies:

```
snapmirror release -relationship-info-only true -destination-path  
dest_SVM:dest_volume
```

```
cluster1::>snapmirror release -relationship-info-only true  
-destination-path vs1_dr:vol1
```

- d. From the destination cluster, create an asynchronous SnapMirror relationship:

```
snapmirror create -source-path src_SVM:src_volume -destination-path dest_SVM:dest_volume -policy MirrorAllSnapshots
```

```
cluster2::>snapmirror create -source-path vs1:vol1 -destination-path vs1_dr:vol1 -policy sync
```

- e. Resynchronize the SnapMirror Synchronous relationship:

```
snapmirror resync -destination-path dest_SVM:dest_volume
```

```
cluster2::>snapmirror resync -destination-path vs1_dr:vol1
```

= Convert the mode of a SnapMirror Synchronous relationship

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

Beginning with ONTAP 9.5, SnapMirror Synchronous relationships are supported. You can convert the mode of a SnapMirror Synchronous relationship from StrictSync to Sync or vice versa.

About this task

You cannot modify the policy of a Snapmirror Synchronous relationship to convert its mode.

Steps

1. From the destination cluster, quiesce the existing SnapMirror Synchronous relationship:

```
snapmirror quiesce -destination-path dest_SVM:dest_volume
```

```
cluster2::> snapmirror quiesce -destination-path vs1_dr:vol1
```

2. From the destination cluster, delete the existing SnapMirror Synchronous relationship:

```
snapmirror delete -destination-path dest_SVM:dest_volume
```

```
cluster2::> snapmirror delete -destination-path vs1_dr:vol1
```

3. From the source cluster, release the SnapMirror relationship without deleting the common Snapshot copies:

```
snapmirror release -relationship-info-only true -destination-path dest_SVM:dest_volume
```

```
cluster1::> snapmirror release -relationship-info-only true  
-destination-path vs1_dr:vol1
```

4. From the destination cluster, create a SnapMirror Synchronous relationship by specifying the mode to which you want to convert the SnapMirror Synchronous relationship:

```
snapmirror create -source-path vs1:vol1 -destination-path  
dest_SVM:dest_volume -policy Sync|StrictSync
```

```
cluster2::> snapmirror create -source-path vs1:vol1 -destination  
-path vs1_dr:vol1 -policy Sync
```

5. From the destination cluster, resynchronize the SnapMirror relationship:

```
snapmirror resync -destination-path dest_SVM:dest_volume
```

```
cluster2::> snapmirror resync -destination-path vs1_dr:vol1
```

= Serve data from a SnapMirror DR destination volume

= Make the destination volume writeable

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You need to make the destination volume writeable before you can serve data from the volume to clients. You can use the `snapmirror quiesce` command to stop scheduled transfers to the destination, the `snapmirror abort` command to stop ongoing transfers, and the `snapmirror break` command to make the destination writeable.

About this task

You must perform this task from the destination SVM or the destination cluster.

Steps

1. Stop scheduled transfers to the destination:

```
snapmirror quiesce -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

The following example stops scheduled transfers between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror quiesce -source-path svm1:volA  
-destination-path svm_backup:volA_dst
```

2. Stop ongoing transfers to the destination:

```
snapmirror abort -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

This step is not required for SnapMirror Synchronous relationships (supported beginning with ONTAP 9.5).

+

The following example stops ongoing transfers between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

+

```
cluster_dst::> snapmirror abort -source-path svm1:volA -destination
-path svm_backup:volA_dst
```

1. Break the SnapMirror DR relationship:

```
snapmirror break -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

The following example breaks the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror break -source-path svm1:volA -destination
-path svm_backup:volA_dst
```

== Other ways to do this in ONTAP

To perform these tasks with...	See this content...
The redesigned System Manager (available with ONTAP 9.7 and later)	Serve data from a SnapMirror destination
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume disaster recovery overview

= Configure the destination volume for data access

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

After making the destination volume writeable, you must configure the volume for data access. NAS clients, NVMe subsystem, and SAN hosts can access the data from the destination volume until the source volume is reactivated.

NAS environment:

1. Mount the NAS volume to the namespace using the same junction path that the source volume was mounted to in the source SVM.
2. Apply the appropriate ACLs to the SMB shares at the destination volume.
3. Assign the NFS export policies to the destination volume.

4. Apply the quota rules to the destination volume.
5. Redirect clients to the destination volume.
6. Remount the NFS and SMB shares on the clients.

SAN environment:

1. Map the LUNs in the volume to the appropriate initiator group.
2. For iSCSI, create iSCSI sessions from the SAN host initiators to the SAN LIFs.
3. On the SAN client, perform a storage re-scan to detect the connected LUNs.

For information about NVMe environment, see [SAN administration](#).

= Reactivate the original source volume

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can reestablish the original data protection relationship between the source and destination volumes when you no longer need to serve data from the destination.

About this task

- The procedure below assumes that the baseline in the original source volume is intact. If the baseline is not intact, you must create and initialize the relationship between the volume you are serving data from and the original source volume before performing the procedure.
- Background preparation and the data warehousing phase of an XDP SnapMirror relationship can take a long time. It is not uncommon to see the SnapMirror relationship reporting the status "preparing" for an extended time period.

Steps

1. Delete the original data protection relationship:

```
snapmirror delete -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

The following example deletes the relationship between the original source volume, `volA` on `svm1`, and the volume you are serving data from, `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror delete -source-path svm1:volA -destination
-path svm_backup:volA_dst
```

2. Reverse the original data protection relationship:

```
snapmirror resync -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the original source SVM or the original source cluster. Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours. The command fails if a common Snapshot copy does not exist on the source and destination. Use `snapmirror initialize` to re-initialize the relationship.

+

The following example reverses the relationship between the original source volume, `volA` on `svm1`, and the volume you are serving data from, `volA_dst` on `svm_backup`:

+

```
cluster_src::> snapmirror resync -source-path svm_backup:volA_dst  
-destination-path svm1:volA
```

1. When you are ready to reestablish data access to the original source, stop access to the original destination volume. One way to do this is to stop the original destination SVM:

```
vserver stop -vserver SVM
```

For complete command syntax, see the man page.

You must run this command from the original destination SVM or the original destination cluster. This command stops user access to the entire original destination SVM. You may want to stop access to the original destination volume using other methods.

+

The following example stops the original destination SVM:

+

```
cluster_dst::> vserver stop svm_backup
```

1. Update the reversed relationship:

```
snapmirror update -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the original source SVM or the original source cluster.

+

The following example updates the relationship between the volume you are serving data from, `volA_dst` on `svm_backup`, and the original source volume, `volA` on `svm1`:

+

```
cluster_src::> snapmirror update -source-path svm_backup:volA_dst  
-destination-path svm1:volA
```

1. From the original source SVM or the original source cluster, stop scheduled transfers for the reversed relationship:

```
snapmirror quiesce -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the original source SVM or the original source cluster.

+

The following example stops scheduled transfers between the original destination volume, `volA_dst` on `svm_backup`, and the original source volume, `volA` on `svm1`:

+

```
cluster_src::> snapmirror quiesce -source-path svm_backup:volA_dst  
-destination-path svm1:volA
```

1. When the final update is complete and the relationship indicates "Quiesced" for the relationship status, run the following command from the original source SVM or the original source cluster to break the reversed relationship::

```
snapmirror break -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the original source SVM or the source cluster.

+

The following example breaks the relationship between the original destination volume, `volA_dst` on `svm_backup`, and the original source volume, `volA` on `svm1`:

+

```
cluster_src::> snapmirror break -source-path svm_backup:volA_dst  
-destination-path svm1:volA
```

1. From the original source SVM or the original source cluster, delete the reversed data protection relationship:

```
snapmirror delete -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the original source SVM or the original source cluster.

+

The following example deletes the reversed relationship between the original source volume, `volA` on `svm1`, and the volume you are serving data from, `volA_dst` on `svm_backup`:

+

```
cluster_src::> snapmirror delete -source-path svm_backup:volA_dst  
-destination-path svm1:volA
```

1. Release the reversed relationship from the original destination SVM or the original destination cluster.

```
snapmirror release -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ...
```

You must run this command from the original destination SVM or the original destination cluster.

+

The following example releases the reversed relationship between the original destination volume, `volA_dst` on `svm_backup`, and the original source volume, `volA` on `svm1`:

```
cluster_dst::> snapmirror release -source-path svm_backup:volA_dst  
-destination-path svm1:volA
```

1. If needed, start the original destination SVM:

```
vserver start -vserver SVM
```

For complete command syntax, see the man page.

The following example starts the original destination SVM:

```
cluster_dst::> vserver start svm_backup
```

2. Reestablish the original data protection relationship from the original destination:

```
snapmirror resync -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

The following example reestablishes the relationship between the original source volume, `volA` on `svm1`, and the original destination volume, `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror resync -source-path svm1:volA -destination  
-path svm_backup:volA_dst
```

After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created. For complete command syntax, see the man page.

= Restore files from a SnapMirror destination volume

= Restore a single file, LUN, or NVMe namespace from a SnapMirror destination
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can restore a single file, LUN, a set of files or LUNs from a Snapshot copy, or an NVMe namespace from a SnapMirror destination volume. Beginning with ONTAP 9.7, you can also restore NVMe namespaces from a SnapMirror Synchronous destination. You can restore files to the original source volume or to a different volume.

What you'll need

To restore a file or LUN from a SnapMirror Synchronous destination (supported beginning with ONTAP 9.5), you must first delete and release the relationship.

About this task

The volume to which you are restoring files or LUNs (the destination volume) must be a read-write volume:

- SnapMirror performs an *incremental restore* if the source and destination volumes have a common Snapshot copy (as is typically the case when you are restoring to the original source volume).
- Otherwise, SnapMirror performs a *baseline restore*, in which the specified Snapshot copy and all the data blocks it references are transferred to the destination volume.

Steps

1. List the Snapshot copies in the destination volume:

```
volume snapshot show -vserver SVM -volume volume
```

For complete command syntax, see the man page.

The following example shows the Snapshot copies on the vserverB:secondary1 destination:

```
cluster_dst::> volume snapshot show -vserver vserverB -volume  
secondary1  
  
Vserver      Volume       Snapshot           State    Size  
Total% Used%  
-----  -----  -----  -----  -----  
-----  -----  
vserverB     secondary1  hourly.2013-01-25_0005  valid   224KB  0%  
0%  
          daily.2013-01-25_0010  valid   92KB   0%  
0%  
          hourly.2013-01-25_0105  valid   228KB  0%  
0%  
          hourly.2013-01-25_0205  valid   236KB  0%  
0%  
          hourly.2013-01-25_0305  valid   244KB  0%  
0%  
          hourly.2013-01-25_0405  valid   244KB  0%  
0%  
          hourly.2013-01-25_0505  valid   244KB  0%  
0%  
  
7 entries were displayed.
```

2. Restore a single file or LUN or a set of files or LUNs from a Snapshot copy in a SnapMirror destination volume:

```
snapmirror restore -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ... -source-snapshot
snapshot -file-list source_file_path,@destination_file_path
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

+

The following command restores the files `file1` and `file2` from the Snapshot copy `daily.2013-01-25_0010` in the original destination volume `secondary1`, to the same location in the active file system of the original source volume `primary1`:

+

```
cluster_dst::> snapmirror restore -source-path vserverB:secondary1  
-destination-path vserverA:primary1 -source-snapshot daily.2013-01-  
25_0010 -file-list /dir1/file1,/dir2/file2
```

```
[Job 3479] Job is queued: snapmirror restore for the relationship with  
destination vserverA:primary1
```

+

The following command restores the files `file1` and `file2` from the Snapshot copy `daily.2013-01-25_0010` in the original destination volume `secondary1`, to a different location in the active file system of the original source volume `primary1`.

+

The destination file path begins with the `@` symbol followed by the path of the file from the root of the original source volume. In this example, `file1` is restored to `/dir1/file1.new` and `file2` is restored to `/dir2.new/file2` on `primary1`:

+

```
cluster_dst::> snapmirror restore -source-path vserverB:secondary1  
-destination-path vserverA:primary1 -source-snapshot daily.2013-01-  
25_0010 -file-list  
/dir/file1,@/dir1/file1.new,/dir2/file2,@/dir2.new/file2
```

```
[Job 3479] Job is queued: snapmirror restore for the relationship with  
destination vserverA:primary1
```

+

The following command restores the files `file1` and `file3` from the Snapshot copy `daily.2013-01-25_0010` in the original destination volume `secondary1`, to different locations in the active file system of the original source volume `primary1`, and restores `file2` from `snap1` to the same location in the active file system of `primary1`.

+

In this example, the file `file1` is restored to `/dir1/file1.new` and `file3` is restored to `/dir3.new/file3`:

+

```
cluster_dst::> snapmirror restore -source-path vserverB:secondary1  
-destination-path vserverA:primary1 -source-snapshot daily.2013-01-  
25_0010 -file-list  
/dir/file1,@/dir1/file1.new,/dir2/file2,/dir3/file3,@/dir3.new/file3
```

```
[Job 3479] Job is queued: snapmirror restore for the relationship with  
destination vserverA:primary1
```

= Restore the contents of a volume from a SnapMirror destination

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can restore the contents of an entire volume from a Snapshot copy in a SnapMirror destination volume. You can restore the volume's contents to the original source volume or to a different volume.

About this task

The destination volume for the restore operation must be one of the following:

- A read-write volume, in which case SnapMirror performs an *incremental restore*, provided that the source and destination volumes have a common Snapshot copy (as is typically the case when you are restoring to the original source volume).

The command fails if there is not a common Snapshot copy. You cannot restore the contents of a volume to an empty read-write volume.

- An empty data protection volume, in which case SnapMirror performs a *baseline restore*, in which the specified Snapshot copy and all the data blocks it references are transferred to the source volume.

Restoring the contents of a volume is a disruptive operation. SMB traffic must not be running on the SnapVault primary volume when a restore operation is running.

If the destination volume for the restore operation has compression enabled, and the source volume does not have compression enabled, disable compression on the destination volume. You need to re-enable compression after the restore operation is complete.

Any quota rules defined for the destination volume are deactivated before the restore is performed. You can use the `volume quota modify` command to reactivate quota rules after the restore operation is complete.

Steps

1. List the Snapshot copies in the destination volume:

```
volume snapshot show -vserver SVM -volume volume
```

For complete command syntax, see the man page.

The following example shows the Snapshot copies on the `vserverB:secondary1` destination:

```
cluster_dst::> volume snapshot show -vserver vserverB -volume
secondary1

Vserver      Volume      Snapshot          State   Size
Total% Used%
-----  -----  -----  -----  -----  -----
-----  -----  -----
vserverB    secondary1  hourly.2013-01-25_0005  valid   224KB  0%
0%           daily.2013-01-25_0010   valid   92KB   0%
0%           hourly.2013-01-25_0105  valid   228KB  0%
0%           hourly.2013-01-25_0205  valid   236KB  0%
0%           hourly.2013-01-25_0305  valid   244KB  0%
0%           hourly.2013-01-25_0405  valid   244KB  0%
0%           hourly.2013-01-25_0505  valid   244KB  0%
0%

7 entries were displayed.
```

2. Restore the contents of a volume from a Snapshot copy in a SnapMirror destination volume:

```
snapmirror restore -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ... -source-snapshot
snapshot
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

+

The following command restores the contents of the original source volume `primary1` from the Snapshot copy `daily.2013-01-25_0010` in the original destination volume `secondary1`:

+

```
cluster_dst::> snapmirror restore -source-path vserverB:secondary1  
-destination-path vserverA:primary1 -source-snapshot daily.2013-01-  
25_0010
```

Warning: All data newer than Snapshot copy `daily.2013-01-25_0010` on volume `vserverA:primary1` will be deleted.

Do you want to continue? {y|n}: y

```
[Job 34] Job is queued: snapmirror restore from source  
vserverB:secondary1 for the snapshot daily.2013-01-25_0010.
```

1. Remount the restored volume and restart all applications that use the volume.

== Other ways to do this in ONTAP

To perform these tasks with...	See this content...
The redesigned System Manager (available with ONTAP 9.7 and later)	Restore a volume from an earlier Snapshot copy
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume restore using SnapVault overview

= Update a replication relationship manually

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You might need to update a replication relationship manually if an update fails because the source volume has been moved.

About this task

SnapMirror aborts any transfers from a moved source volume until you update the replication relationship manually.

Beginning with ONTAP 9.5, SnapMirror Synchronous relationships are supported. Although the source and destination volumes are in sync at all times in these relationships, the view from the secondary cluster is synchronized with the primary only on an hourly basis. If you want to view the point-in-time data at the destination, you should perform a manual update by running the `snapmirror update` command.

Step

1. Update a replication relationship manually:

```
snapmirror update -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster. The command fails if a common Snapshot copy does not exist on the source and destination. Use `snapmirror initialize` to re-initialize the relationship.

+

The following example updates the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

+

```
cluster_src::> snapmirror update -source-path svm1:volA -destination
-path svm_backup:volA_dst
```

= Resynchronize a replication relationship

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You need to resynchronize a replication relationship after you make a destination volume writeable, after an update fails because a common Snapshot copy does not exist on the source and destination volumes, or if you want to change the replication policy for the relationship.

About this task

- Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.
- Volumes that are part of a fan-out or cascade configuration can take longer to resynchronize. It is not uncommon to see the SnapMirror relationship reporting the status "preparing" for an extended time period.

Step

1. Resync the source and destination volumes:

```
snapmirror resync -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ... -type DP|XDP -schedule
schedule -policy policy
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

+

The following example resyncs the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

+

```
cluster_dst::> snapmirror resync -source-path svm1:volA -destination
-path svm_backup:volA_dst
```

= Delete a volume replication relationship

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use the `snapmirror delete` and `snapmirror release` commands to delete a volume replication relationship. You can then delete unneeded destination volumes manually.

About this task

The `snapmirror release` command deletes any SnapMirror-created Snapshot copies from the source. You can use the `-relationship-info-only` option to preserve the Snapshot copies.

Steps

1. Quiesce the replication relationship:

```
snapmirror quiesce -destination-path SVM:volume|cluster://SVM/volume
```

```
cluster_dst::> snapmirror quiesce -destination-path
svm_backup:volA_dst
```

2. (Optional) Break the replication relationship if you require the destination volume to be a read/write volume. You can skip this step if you plan to delete the destination volume or if you don't need the volume to be read/write:

```
snapmirror break -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

```
cluster_dst::> snapmirror break -source-path svm1:volA -destination
-path svm_backup:volA_dst
```

3. Delete the replication relationship:

```
snapmirror delete -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination cluster or destination SVM.

+

The following example deletes the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

+

```
cluster_dst::> snapmirror delete -source-path svm1:volA -destination  
-path svm_backup:volA_dst
```

1. Release replication relationship information from the source SVM:

```
snapmirror release -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the source cluster or source SVM.

+

The following example releases information for the specified replication relationship from the source SVM svm1:

+

```
cluster_src::> snapmirror release -source-path svm1:volA -destination  
-path svm_backup:volA_dst
```

= Manage storage efficiency

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

SnapMirror preserves storage efficiency on the source and destination volumes, with one exception, when postprocess data compression is enabled on the destination. In that case, all storage efficiency is lost on the destination. To correct this issue, you need to disable postprocess compression on the destination, update the relationship manually, and re-enable storage efficiency.

What you'll need

- The source and destination clusters and SVMs must be peered.

[Cluster and SVM peering](#)

- You must disable postprocess compression on the destination.

About this task

You can use the `volume efficiency show` command to determine whether efficiency is enabled on a volume. For more information, see the man pages.

You can check if SnapMirror is maintaining storage efficiency by viewing the SnapMirror audit logs and locating the transfer description. If the transfer description displays `transfer_desc=Logical Transfer`, SnapMirror is not maintaining storage efficiency. If the transfer description displays `transfer_desc=Logical Transfer with Storage Efficiency`, SnapMirror is maintaining storage efficiency. For example:

```
Fri May 22 02:13:02 CDT 2020 ScheduledUpdate[May 22 02:12:00]:cc0fbc29-  
b665-11e5-a626-00a09860c273 Operation-Uuid=39fbef48-550a-4282-a906-  
df35632c73a1 Group=none Operation-Cookie=0 action=End  
source=<sourcepath> destination=<destpath> status=Success  
bytes_transferred=117080571 network_compression_ratio=1.0:1  
transfer_desc=Logical Transfer - Optimized Directory Mode
```

Logical Transfer with storage

Beginning with ONTAP 9.3, manual update is no longer required to re-enable storage efficiency. If

SnapMirror detects that postprocess compression has been disabled, it automatically re-enables storage efficiency at the next scheduled update. Both the source and the destination must be running ONTAP 9.3.

Beginning with ONTAP 9.3, AFF systems manage storage efficiency settings differently from FAS systems after a destination volume is made writeable:

- After you make a destination volume writeable using the `snapmirror break` command, the caching policy on the volume is automatically set to “auto” (the default).

This behavior is applicable to FlexVol volumes, only, and it does not apply to FlexGroup volumes.

- On resync, the caching policy is automatically set to “none”, and deduplication and inline compression are automatically disabled, regardless of your original settings. You must modify the settings manually as needed.

Manual updates with storage efficiency enabled can be time-consuming. You might want to run the operation in off-peak hours.

Step

1. Update a replication relationship and re-enable storage efficiency:

```
snapmirror update -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ... -enable-storage
-efficiency true
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster. The command fails if a common Snapshot copy does not exist on the source and destination. Use `snapmirror initialize` to re-initialize the relationship.

+

The following example updates the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`, and re-enables storage efficiency:

+

```
cluster_dst::> snapmirror update -source-path svm1:volA -destination
-path svm_backup:volA_dst -enable-storage-efficiency true
```

= Use SnapMirror global throttling

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

Global network throttling is available for all SnapMirror and SnapVault transfers at a per-node level.

About this task

SnapMirror global throttling restricts the bandwidth used by incoming and/or outgoing SnapMirror and SnapVault transfers. The restriction is enforced cluster wide on all nodes in the cluster.

For example, if the outgoing throttle is set to 100 MBps, each node in the cluster will have the outgoing bandwidth set to 100 MBps. If global throttling is disabled, it is disabled on all nodes.

Although data transfer rates are often expressed in bits per second (bps), the throttle values must be entered in kilobytes per second (KBps).

In ONTAP 9.9.1 and earlier releases, the throttle has no effect on `volume move` transfers or load-sharing mirror transfers. Beginning with ONTAP 9.10.0, you can specify an option to throttle a volume move operations. For details, see [How to throttle volume move in ONTAP 9.10 and later](#).

Global throttling works with the per-relationship throttle feature for SnapMirror and SnapVault transfers. The per-relationship throttle is enforced until the combined bandwidth of per-relationship transfers exceeds the value of the global throttle, after which the global throttle is enforced. A throttle value 0 implies that global throttling is disabled.

SnapMirror global throttling has no effect on SnapMirror Synchronous relationships when they are In-Sync. However, the throttle does effect SnapMirror Synchronous relationships when they perform an asynchronous transfer phase such as an initialization operation or after an Out Of Sync event. For this reason, enabling global throttling with SnapMirror Synchronous relationships is not recommended.

Steps

1. Enable global throttling:

```
options -option-name replication.throttle.enable on|off
```

The following example shows how to enable SnapMirror global throttling on `cluster_dst`:

```
cluster_dst::> options -option-name replication.throttle.enable on
```

2. Specify the maximum total bandwidth used by incoming transfers on the destination cluster:

```
options -option-name replication.throttle.incoming.max_kbs KBps
```

The recommended minimum throttle bandwidth is 4 KBps and the maximum is up to 2 TBps. The default value for this option is `unlimited`, which means there is no limit on total bandwidth used.

The following example shows how to set the maximum total bandwidth used by incoming transfers to 100 Mbps:

```
cluster_dst::> options -option-name  
replication.throttle.incoming.max_kbs 12500
```

100 Mbps = 12500 KBps

1. Specify the maximum total bandwidth used by outgoing transfers on the source cluster:

```
options -option-name replication.throttle.outgoing.max_kbs KBps
```

KBps is the maximum transfer rate in kilobytes per second. Valid transfer rate values are 1 to 125000. The default value for this option is `unlimited`, which means there is no limit on total bandwidth used.

The following example shows how to set the maximum total bandwidth used by outgoing transfers to 100 Mbps:

```
cluster_src::> options -option-name  
replication.throttle.outgoing.max_kbs 12500
```

= About SnapMirror SVM replication

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You can use SnapMirror to create a data protection relationship between SVMs. In this type of data protection relationship, all or part of the SVM's configuration, from NFS exports and SMB shares to RBAC, is replicated, as well as the data in the volumes that the SVM owns.

== Supported relationship types

Only data-serving SVMs can be replicated. The following data protection relationship types are supported:

- *SnapMirror DR*, in which the destination typically contains only the Snapshot copies currently on the source.

Beginning with ONTAP 9.9.1, this behavior changes when you are using the mirror-vault policy.

Beginning with ONTAP 9.9.1, you can create different Snapshot policies on the source and destination, and the Snapshot copies on the destination are not overwritten by Snapshot copies on the source:

- They are not overwritten from the source to the destination during normal scheduled operations, updates and resync
- They are not deleted during break operations.

- They are not deleted during flip-resync operations.

When you configure an SVM DR relationship using the mirror-vault policy using ONTAP 9.9.1 and later, the policy behaves as follows:

- User-defined Snapshot copy policies at the source are not copied to the destination.
- System-defined Snapshot copy policies are not copied to the destination.
- Volume association with user and system defined Snapshot policies are not copied to the destination.

SVM.

- Beginning with ONTAP 9.2, *SnapMirror unified replication*, in which the destination is configured for both DR and long-term retention.

Details about these relationship types can be found here: [Understanding SnapMirror volume replication](#).

The *policy type* of the replication policy determines the type of relationship it supports. The following table shows the available policy types.

Policy type	Relationship type
async-mirror	SnapMirror DR
mirror-vault	Unified replication

== XDP replaces DP as the SVM replication default in ONTAP 9.4

Beginning with ONTAP 9.4, SVM data protection relationships default to XDP mode. SVM data protection relationships continue to default to DP mode in ONTAP 9.3 and earlier.

Existing relationships are not affected by the new default. If a relationship is already of type DP, it will continue to be of type DP. The following table shows the behavior you can expect.

If you specify...	The type is...	The default policy (if you do not specify a policy) is...
DP	XDP	MirrorAllSnapshots (SnapMirror DR)
Nothing	XDP	MirrorAllSnapshots (SnapMirror DR)
XDP	XDP	MirrorAndVault (Unified replication)

Details about the changes in the default can be found here: [XDP replaces DP as the SnapMirror default](#).

Version-independence is not supported for SVM replication. In an SVM DR configuration, the destination SVM must be on a cluster running the same ONTAP version as the source SVM cluster to support failover and fail back operations.

Compatible ONTAP versions for SnapMirror relationships

== How SVM configurations are replicated

The content of an SVM replication relationship is determined by the interaction of the following fields:

- The `-identity-preserve true` option of the `snapmirror create` command replicates the entire SVM configuration.
- The `-identity-preserve false` option replicates only the volumes and authentication and authorization configurations of the SVM, and the protocol and name service settings listed in [Configurations replicated in SVM DR relationships](#).
- The `-discard-configs network` option of the `snapmirror policy create` command excludes LIFs and related network settings from SVM replication, for use in cases where the source and destination SVMs are in different subnets.
 - The `-vserver-dr-protection unprotected` option of the `volume modify` command excludes the specified volume from SVM replication.

Otherwise, SVM replication is almost identical to volume replication. You can use virtually the same workflow for SVM replication as you use for volume replication.

== Support details

The following table shows support details for SnapMirror SVM replication.

Resource or feature	Support details
Relationship types	<ul style="list-style-type: none">• SnapMirror DR• Beginning with ONTAP 9.2, SnapMirror unified replication
Replication scope	Intercluster only. You cannot replicate SVMs in the same cluster.
Version-independence	Not supported.
Deployment types	<ul style="list-style-type: none">• Single source to single destination• Beginning with ONTAP 9.4, fan-out. You can fan-out to two destinations only. <p>By default, only one <code>-identity-preserve true</code> relationship is allowed per source SVM.</p>
Autonomous Ransomware Protection	<ul style="list-style-type: none">• Supported beginning with ONTAP 9.12.1. For more information, see Autonomous Ransomware Protection

Volume encryption	<ul style="list-style-type: none"> Encrypted volumes on the source are encrypted on the destination. Onboard Key Manager or KMIP servers must be configured on the destination. New encryption keys are generated at the destination. If the destination does not contain a node that supports volume encryption, replication succeeds, but the destination volumes are not encrypted.
FabricPool	Beginning with ONTAP 9.6, SnapMirror SVM replication is supported with FabricPools.
MetroCluster	<p>Beginning with ONTAP 9.11.1, both sides of a SVM DR relationship within a MetroCluster configuration can act as a source for additional SVM DR configurations.</p> <p>Beginning with ONTAP 9.5, SnapMirror SVM replication is supported on MetroCluster configurations.</p> <ul style="list-style-type: none"> A MetroCluster configuration cannot be the destination of an SVM DR relationship. Only an active SVM within a MetroCluster configuration can be the source of an SVM DR relationship. <p>A source can be a sync-source SVM before switchover or a sync-destination SVM after switchover.</p> <ul style="list-style-type: none"> When a MetroCluster configuration is in a steady state, the MetroCluster sync-destination SVM cannot be the source of an SVM DR relationship, since the volumes are not online. When the sync-source SVM is the source of an SVM DR relationship, the source SVM DR relationship information is replicated to the MetroCluster partner. During the switchover and switchback processes, replication to the SVM DR destination might fail. <p>However, after the switchover or switchback process completes, the next SVM DR scheduled updates will succeed.</p>

SnapMirror Synchronous	Not supported with SVM DR.
------------------------	----------------------------

== Configurations replicated in SVM DR relationships

The following table shows the interaction of the `snapmirror create -identity-preserve` option and the `snapmirror policy create -discard-configs network` option:

Configuration replicated		-identity-preserve true	-identity-preserve false
		Policy without -discard -configs network set	Policy with -discard -configs network set

== SVM DR storage limits

The following table shows the recommended maximum number of volumes and SVM DR relationships supported per storage object. You should be aware that limits are often platform dependent. Refer to the [Hardware Universe](#) to learn the limits for your specific configuration.

Storage object	Limit
SVM	300 Flexible volumes
HA pair	1,000 Flexible Volumes
Cluster	128 SVM DR relationships

= Manage SnapMirror SVM replication

= Replicate SVM configurations

= SnapMirror SVM replication workflow

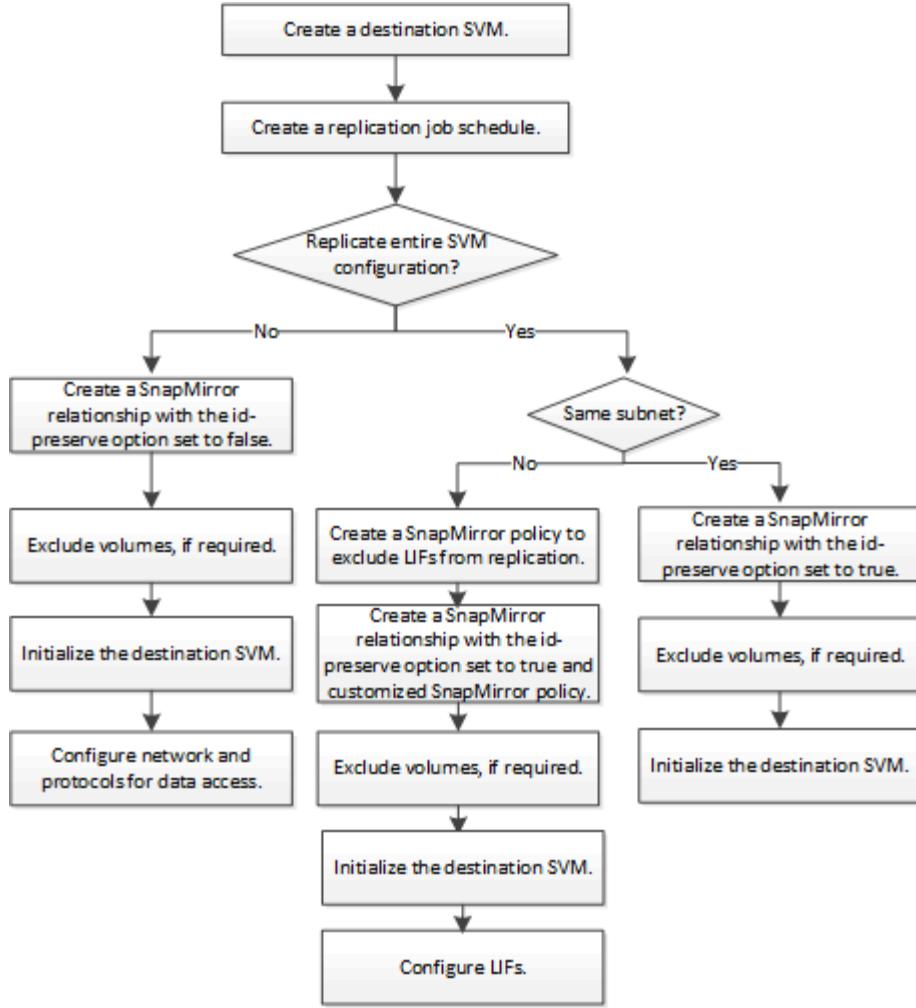

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source//encryption-at-rest//media/

SnapMirror SVM replication involves creating the destination SVM, creating a replication job schedule, and creating and initializing a SnapMirror relationship.

This workflow assumes that you are already using a default policy or a custom replication policy.

= Criteria for placing volumes on destination SVMs

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

When replicating volumes from the source SVM to the destination SVM, it's important to know the criteria for selecting aggregates.

Aggregates are selected based on the following criteria:

- Volumes are always placed on non-root aggregates.
- Non-root aggregates are selected based on the available free space and the number of volumes already hosted on the aggregate.

Aggregates with more free space and fewer volumes are given priority. The aggregate with the highest priority is selected.

- Source volumes on FabricPool aggregates are placed on FabricPool aggregates on the destination with the same tiering-policy.
- If a volume on the source SVM is located on a Flash Pool aggregate, then the volume is placed on a Flash Pool aggregate on the destination SVM, if such an aggregate exists and has enough free space.

- If the `-space-guarantee` option of the volume that is replicated is set to `volume`, only aggregates with free space greater than the volume size are considered.
- The volume size grows automatically on the destination SVM during replication, based on the source volume size.

If you want to pre-reserve the size on the destination SVM, you must resize the volume. The volume size does not shrink automatically on the destination SVM based on the source SVM.

If you want to move a volume from one aggregate to another, you can use the `volume move` command on the destination SVM.

= Replicate an entire SVM configuration
 :icons: font
 :relative_path: ./data-protection/
 :imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

You can use the `-identity-preserve true` option of the `snapmirror create` command to replicate an entire SVM configuration.

Before you begin

The source and destination clusters and SVMs must be peered.

For more information, see [Create a cluster peer relationship](#) and [Create an SVM intercluster peer relationship](#).

For complete command syntax, see the man page.

About this task

This workflow assumes that you are already using a default policy or a custom replication policy.

Beginning with ONTAP 9.9.1, when you use the mirror-vault policy, you can create different Snapshot policies on the source and destination SVM, and the Snapshot copies on the destination are not overwritten by Snapshot copies on the source. For more information, see [Understanding SnapMirror SVM replication](#).

Steps

1. Create a destination SVM:

```
vserver create -vserver SVM_name -subtype dp-destination
```

The SVM name must be unique across the source and destination clusters.

The following example creates a destination SVM named `svm_backup`:

```
cluster_dst:> vserver create -vserver svm_backup -subtype dp-destination
```

2. From the destination cluster, create an SVM peer relationship using the `vserver peer create` command.

For more information, see [Create an SVM intercluster peer relationship](#).

3. Create a replication job schedule:

```
job schedule cron create -name job_name -month month -dayofweek day_of_week  
-day day_of_month -hour hour -minute minute
```

For **-month**, **-dayofweek**, and **-hour**, you can specify **all** to run the job every month, day of the week, and hour, respectively.

The minimum supported schedule (RPO) for FlexVol volumes in an SVM SnapMirror relationship is 15 minutes. The minimum supported schedule (RPO) for FlexGroup volumes in an SVM SnapMirror relationship is 30 minutes.

+

The following example creates a job schedule named `my_weekly` that runs on Saturdays at 3:00 a.m.:

+

```
cluster_dst::> job schedule cron create -name my_weekly -dayofweek  
saturday -hour 3 -minute 0
```

1. From the destination SVM or the destination cluster, create a replication relationship:

```
snapmirror create -source-path SVM_name: -destination-path SVM_name: -type  
DP|XDP -schedule schedule -policy policy -identity-preserve true
```

You must enter a colon (:) after the SVM name in the **-source-path** and **-destination-path** options.

+

The following example creates a SnapMirror DR relationship using the default `MirrorAllSnapshots` policy:

+

```
cluster_dst:> snapmirror create -source-path svm1: -destination-path
svm_backup: -type XDP -schedule my_daily -policy MirrorAllSnapshots
-identity-preserve true
```

+

The following example creates a unified replication relationship using the default `MirrorAndVault` policy:

+

```
cluster_dst:> snapmirror create -source-path svm1: -destination-path
svm_backup: -type XDP -schedule my_daily -policy MirrorAndVault
-identity-preserve true
```

+

Assuming you have created a custom policy with the policy type `async-mirror`, the following example creates a SnapMirror DR relationship:

+

```
cluster_dst:> snapmirror create -source-path svm1: -destination-path
svm_backup: -type XDP -schedule my_daily -policy my_mirrored -identity
-preserve true
```

+

Assuming you have created a custom policy with the policy type `mirror-vault`, the following example creates a unified replication relationship:

+

```
cluster_dst:> snapmirror create -source-path svm1: -destination-path
svm_backup: -type XDP -schedule my_daily -policy my_unified -identity
-preserve true
```

1. Stop the destination SVM:

```
vserver stop
```

SVM name

The following example stops a destination SVM named dvs1:

```
cluster_dst:> vserver stop -vserver dvs1
```

2. From the destination SVM or the destination cluster, initialize the SVM replication relationship: +

```
snapmirror initialize -source-path SVM_name: -destination-path SVM_name:
```

The following example initializes the relationship between the source SVM, svm1, and the destination SVM, svm_backup:

```
cluster_dst:> snapmirror initialize -source-path svm1: -destination-path svm_backup:
```

= Exclude LIFs and related network settings from SVM replication
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

If the source and destination SVMs are in different subnets, you can use the `-discard-configs` network option of the `snapmirror policy create` command to exclude LIFs and related network settings from SVM replication.

What you'll need

The source and destination clusters and SVMs must be peered.

For more information, see [Create a cluster peer relationship](#) and [Create an SVM intercluster peer relationship](#).

About this task

The `-identity-preserve` option of the `snapmirror create` command must be set to `true` when you create the SVM replication relationship.

For complete command syntax, see the man page.

Steps

1. Create a destination SVM:

```
vserver create -vserver SVM -subtype dp-destination
```

The SVM name must be unique across the source and destination clusters.

The following example creates a destination SVM named `svm_backup`:

```
cluster_dst:> vserver create -vserver svm_backup -subtype dp-destination
```

- From the destination cluster, create an SVM peer relationship using the `vserver peer create` command.

For more information, see [Create an SVM intercluster peer relationship](#).

- Create a job schedule:

```
job schedule cron create -name job_name -month month -dayofweek day_of_week  
-day day_of_month -hour hour -minute minute
```

For `-month`, `-dayofweek`, and `-hour`, you can specify `all` to run the job every month, day of the week, and hour, respectively.

The minimum supported schedule (RPO) for FlexVol volumes in an SVM SnapMirror relationship is 15 minutes. The minimum supported schedule (RPO) for FlexGroup volumes in an SVM SnapMirror relationship is 30 minutes.

+

The following example creates a job schedule named `my_weekly` that runs on Saturdays at 3:00 a.m.:

+

```
cluster_dst::> job schedule cron create -name my_weekly -dayofweek  
"Saturday" -hour 3 -minute 0
```

1. Create a custom replication policy:

```
snapmirror policy create -vserver SVM -policy policy -type async-  
mirror|vault|mirror-vault -comment comment -tries transfer_tries -transfer  
-priority low|normal -is-network-compression-enabled true|false -discard  
-configs network
```

For complete command syntax, see the man page.

The following example creates a custom replication policy for SnapMirror DR that excludes LIFs:

```
cluster_dst::> snapmirror policy create -vserver svm1 -policy  
DR_exclude_LIFs -type async-mirror -discard-configs network
```

The following example creates a custom replication policy for unified replication that excludes LIFs:

```
cluster_dst::> snapmirror policy create -vserver svm1 -policy  
unified_exclude_LIFs -type mirror-vault -discard-configs network
```

2. From the destination SVM or the destination cluster, run the following command to create a replication relationship:

```
snapmirror create -source-path SVM: -destination-path SVM: -type DP|XDP  
-schedule schedule -policy policy -identity-preserve true|false
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the examples below.

+

The following example creates a SnapMirror DR relationship that excludes LIFs:

+

```
cluster_dst::> snapmirror create -source-path svm1: -destination-path
svm_backup: -type XDP -schedule my_daily -policy DR_exclude_LIFs
-identity-preserve true
```

+

The following example creates a SnapMirror unified replication relationship that excludes LIFs:

+

```
cluster_dst::> snapmirror create -source-path svm1: -destination-path
svm_backup: -type XDP -schedule my_daily -policy unified_exclude_LIFs
-identity-preserve true
```

1. Stop the destination SVM:

```
vserver stop
```

SVM name

The following example stops a destination SVM named dvs1:

```
cluster_dst::> vserver stop -vserver dvs1
```

2. From the destination SVM or the destination cluster, initialize a replication relationship:

```
snapmirror initialize -source-path SVM: -destination-path SVM:
```

For complete command syntax, see the man page.

The following example initializes the relationship between the source, *svm1* and the destination, *svm_backup*:

```
cluster_dst::> snapmirror initialize -source-path svm1: -destination
-path svm_backup:
```

After you finish

You must configure the network and protocols on the destination SVM for data access in the event a disaster occurs.

= Exclude network, name service, and other settings from SVM replication

```
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/
```

You can use the `-identity-preserve false` option of the `snapmirror create` command to replicate only the volumes and security configurations of an SVM. Some protocol and name service settings are also preserved.

What you'll need

The source and destination clusters and SVMs must be peered.

For more information, see [Create a cluster peer relationship](#) and [Create an SVM intercluster peer relationship](#).

About this task

For a list of preserved protocol and name service settings, see [Configurations replicated in SVM DR relationships](#).

For complete command syntax, see the man page.

Steps

1. Create a destination SVM:

```
vserver create -vserver SVM -subtype dp-destination
```

The SVM name must be unique across the source and destination clusters.

The following example creates a destination SVM named `svm_backup`:

```
cluster_dst:> vserver create -vserver svm_backup -subtype dp-destination
```

2. From the destination cluster, create an SVM peer relationship using the `vserver peer create` command.

For more information, see [Create an SVM intercluster peer relationship](#).

3. Create a replication job schedule:

```
job schedule cron create -name job_name -month month -dayofweek day_of_week  
-day day_of_month -hour hour -minute minute
```

For `-month`, `-dayofweek`, and `-hour`, you can specify `all` to run the job every month, day of the week, and hour, respectively.

The minimum supported schedule (RPO) for FlexVol volumes in an SVM SnapMirror relationship is 15 minutes. The minimum supported schedule (RPO) for FlexGroup volumes in an SVM SnapMirror relationship is 30 minutes.

+

The following example creates a job schedule named `my_weekly` that runs on Saturdays at 3:00 a.m.:

+

```
cluster_dst::> job schedule cron create -name my_weekly -dayofweek  
"Saturday" -hour 3 -minute 0
```

1. Create a replication relationship that excludes network, name service, and other configuration settings:

```
snapmirror create -source-path SVM: -destination-path SVM: -type DP|XDP  
-schedule schedule -policy policy -identity-preserve false
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the examples below. You must run this command from the destination SVM or the destination cluster.

+

The following example creates a SnapMirror DR relationship using the default `MirrorAllSnapshots` policy. The relationship excludes network, name service, and other configuration settings from SVM replication:

+

```
cluster_dst:> snapmirror create -source-path svm1: -destination-path
svm_backup: -type XDP -schedule my_daily -policy MirrorAllSnapshots
-identity-preserve false
```

+

The following example creates a unified replication relationship using the default `MirrorAndVault` policy. The relationship excludes network, name service, and other configuration settings:

+

```
cluster_dst:> snapmirror create svm1: -destination-path svm_backup:
-type XDP -schedule my_daily -policy MirrorAndVault -identity-preserve
false
```

+

Assuming you have created a custom policy with the policy type `async-mirror`, the following example creates a SnapMirror DR relationship. The relationship excludes network, name service, and other configuration settings from SVM replication:

+

```
cluster_dst:> snapmirror create -source-path svm1: -destination-path
svm_backup: -type XDP -schedule my_daily -policy my_mirrored -identity
-preserve false
```

+

Assuming you have created a custom policy with the policy type `mirror-vault`, the following example creates a unified replication relationship. The relationship excludes network, name service, and other configuration settings from SVM replication:

+

```
cluster_dst:> snapmirror create -source-path svm1: -destination-path
svm_backup: -type XDP -schedule my_daily -policy my_unified -identity
-preserve false
```

1. Stop the destination SVM:

```
vserver stop
```

SVM name

The following example stops a destination SVM named dvs1:

```
destination_cluster::> vserver stop -vserver dvs1
```

2. If you are using SMB, you must also configure an SMB server.

See [SMB only: Creating an SMB server](#).

3. From the destination SVM or the destination cluster, initialize the SVM replication relationship:

```
snapmirror initialize -source-path SVM_name: -destination-path SVM_name:
```

After you finish

You must configure the network and protocols on the destination SVM for data access in the event a disaster occurs.

= Specify aggregates to use for SVM DR relationships

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

After a disaster recovery SVM is created, you can use the `aggr-list` option with `vserver modify` command to limit which aggregates are used to host SVM DR destination volumes.

Step

1. Create a destination SVM:

```
vserver create -vserver SVM -subtype dp-destination
```

2. Modify the disaster recovery SVM's aggr-list to limit the aggregates that are used to host the disaster recovery SVM's volume:

```
cluster_dest::> vserver modify -vserver SVM -aggr-list <comma-separated-list>
```

= SMB only: Create a SMB server

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

If the source SVM has an SMB configuration, and you chose to set `identity-preserve` to `false`, you must create a SMB server for the destination SVM. SMB server is required for some SMB configurations, such as shares during initialization of the SnapMirror relationship.

Steps

1. Start the destination SVM by using the vserver start command.

```
destination_cluster::> vserver start -vserver dvs1  
[Job 30] Job succeeded: DONE
```

2. Verify that the destination SVM is in the running state and subtype is dp-destination by using the vserver show command.

```
destination_cluster::> vserver show  
Vserver      Type      Subtype          Admin      Operational Root  
Aggregate  
-----  
-----  
dvs1        data      dp-destination    running    running      -  
-
```

3. Create a LIF by using the network interface create command.

```
destination_cluster::>network interface create -vserver dvs1 -lif  
NAS1 -role data -data-protocol cifs -home-node destination_cluster-  
01 -home-port a0a-101 -address 192.0.2.128 -netmask 255.255.255.128
```

4. Create a route by using the network route create command.

```
destination_cluster::>network route create -vserver dvs1  
-destination 0.0.0.0/0  
-gateway 192.0.2.1
```

Network management

5. Configure DNS by using the vserver services dns create command.

```
destination_cluster::>vserver services dns create -domains  
mydomain.example.com -vserver  
dvs1 -name-servers 192.0.2.128 -state enabled
```

6. Add the preferred domain controller by using the vserver cifs domain preferred-dc add command.

```
destination_cluster::>vserver cifs domain preferred-dc add -vserver  
dvs1 -preferred-dc  
192.0.2.128 -domain mydomain.example.com
```

7. Create the SMB server by using the `vserver cifs create` command.

```
destination_cluster::>vserver cifs create -vserver dvs1 -domain  
mydomain.example.com  
-cifs-server CIFS1
```

8. Stop the destination SVM by using the `vserver stop` command.

```
destination_cluster::> vserver stop -vserver dvs1  
[Job 46] Job succeeded: DONE
```

= Exclude volumes from SVM replication
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

By default, all RW data volumes of the source SVM are replicated. If you do not want to protect all the volumes on the source SVM, you can use the `-vserver-dr-protection unprotected` option of the `volume modify` command to exclude volumes from SVM replication.

Steps

1. Exclude a volume from SVM replication:

```
volume modify -vserver SVM -volume volume -vserver-dr-protection  
unprotected
```

For complete command syntax, see the man page.

The following example excludes the volume `volA_src` from SVM replication:

```
cluster_src::> volume modify -vserver SVM1 -volume volA_src -vserver  
-dr-protection unprotected
```

If you later want to include a volume in the SVM replication that you originally excluded, run the following command:

```
volume modify -vserver SVM -volume volume -vserver-dr-protection protected
```

The following example includes the volume `volA_src` in the SVM replication:

```
cluster_src::> volume modify -vserver SVM1 -volume volA_src -vserver  
-dr-protection protected
```

2. Create and initialize the SVM replication relationship as described in [Replicating an entire SVM configuration](#).

= Serve data from an SVM DR destination

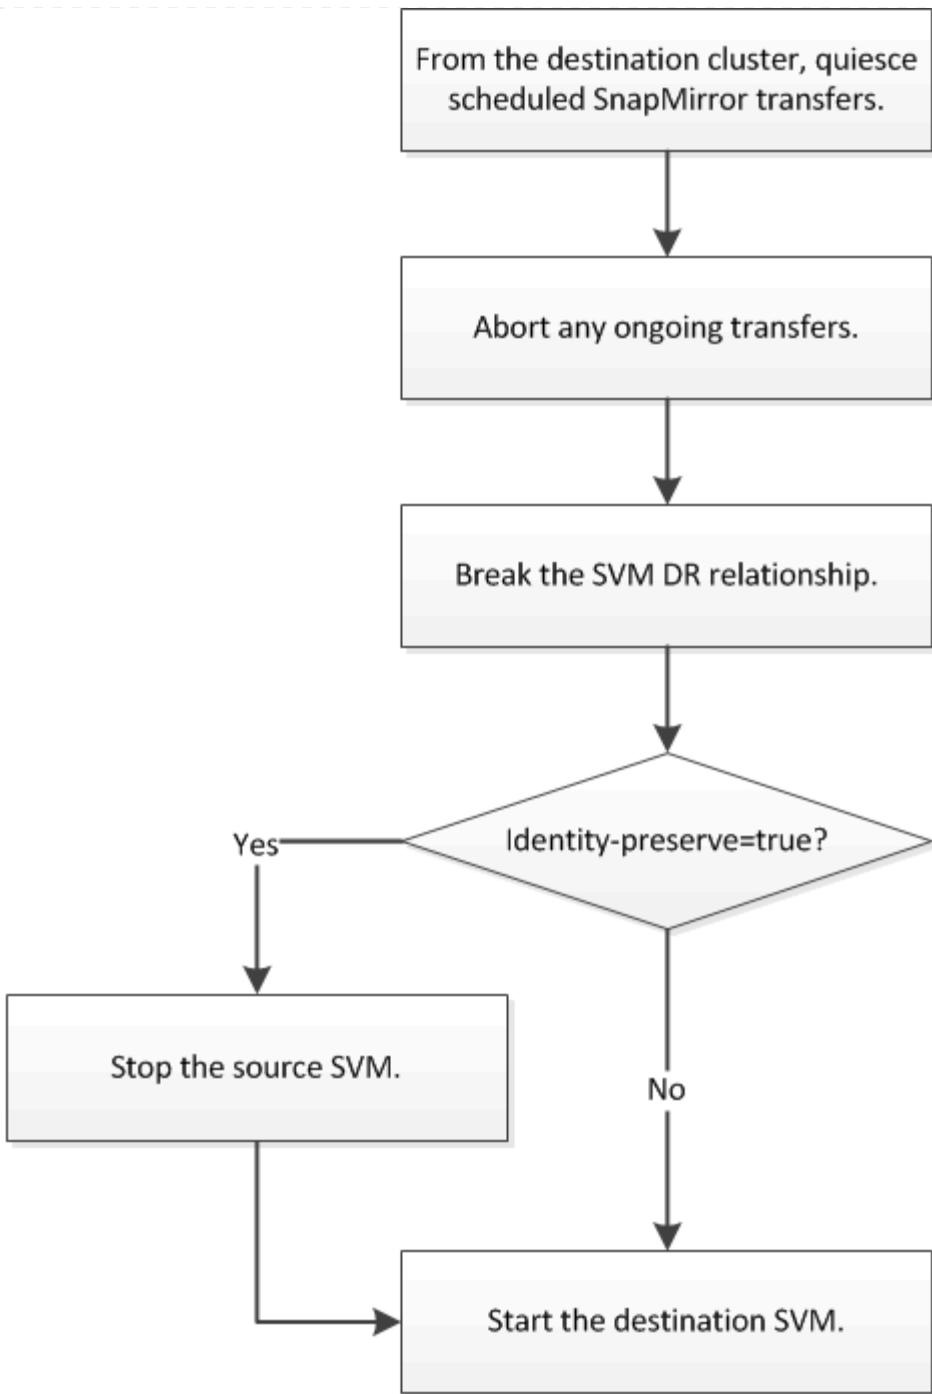

= SVM disaster recovery workflow

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

To recover from a disaster and serve data from the destination SVM, you must activate the destination SVM. Activating the destination SVM involves stopping scheduled SnapMirror transfers, aborting ongoing SnapMirror transfers, breaking the replication relationship, stopping the source SVM, and starting the destination SVM.

= Make SVM destination volumes writeable

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You need to make SVM destination volumes writeable before you can serve data to clients. The procedure is largely identical to the procedure for volume replication, with one exception. If you set `-identity-preserve true` when you created the SVM replication relationship, you must stop the source SVM before activating the destination SVM.

About this task

For complete command syntax, see the man page.

In a disaster recovery scenario, you cannot perform a SnapMirror update from the source SVM to the disaster recovery destination SVM because your source SVM and its data will be inaccessible, and because updates since the last resync might be bad or corrupt.

Steps

1. From the destination SVM or the destination cluster, stop scheduled transfers to the destination:

```
snapmirror quiesce -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the -source-path and -destination-path options. See the example below.

+

The following example stops scheduled transfers between the source SVM `svm1` and the destination SVM `svm_backup`:

+

```
cluster_dst::> snapmirror quiesce -source-path svm1: -destination-path  
svm_backup:
```

1. From the destination SVM or the destination cluster, stop ongoing transfers to the destination:

```
snapmirror abort -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the -source-path and -destination-path options. See the example below.

+

The following example stops ongoing transfers between the source SVM `svm1` and the destination SVM `svm_backup`:

+

```
cluster_dst::> snapmirror abort -source-path svm1: -destination-path  
svm_backup:
```

1. From the destination SVM or the destination cluster, break the replication relationship:

```
snapmirror break -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the -source-path and -destination-path options. See the example below.

+

The following example breaks the relationship between the source SVM `svm1` and the destination SVM `svm_backup`:

+

```
cluster_dst::> snapmirror break -source-path svm1: -destination-path  
svm_backup:
```

1. If you set `-identity-preserve true` when you created the SVM replication relationship, stop the source SVM:

```
vserver stop -vserver SVM
```

The following example stops the source SVM `svm1`:

```
cluster_src::> vserver stop svm1
```

2. Start the destination SVM:

```
vserver start -vserver SVM
```

The following example starts the destination SVM `svm_backup`:

```
cluster_dst::> vserver start svm_backup
```

After you finish

Configure SVM destination volumes for data access, as described in [Configuring the destination volume for data access](#).

= Reactivate the source SVM

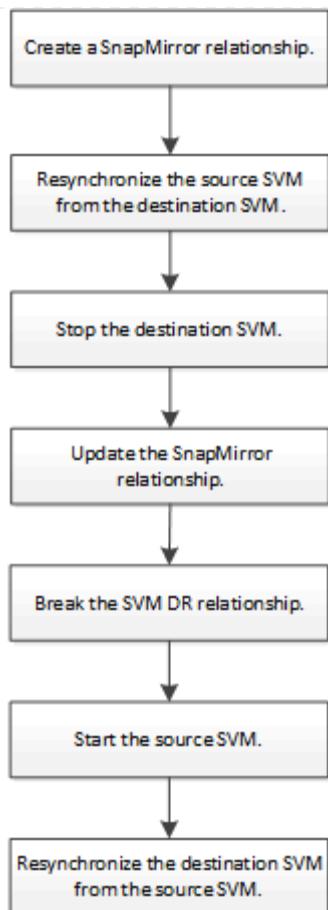

= Source SVM reactivation workflow

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

If the source SVM exists after a disaster, you can reactivate it and protect it by recreating the SVM disaster recovery relationship.

= Reactivate the original source SVM

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

You can reestablish the original data protection relationship between the source and destination SVM when you no longer need to serve data from the destination. The procedure is largely identical to the procedure for volume replication, with one exception. You must stop the destination SVM before-reactivating the source SVM.

What you'll need

If you have increased the size of destination volume while serving data from it, before you reactivate the source volume, you should manually increase max-autosize on the original source volume to ensure it can grow sufficiently.

When a destination volume grows automatically

About this task

Beginning with ONTAP 9.11.1, you can reduce resynchronization time during a disaster recovery rehearsal by using the `-quick-resync true` option of the `snapmirror resync` command while performing a reverse resync of an SVM DR relationship. A quick resync can reduce the time it takes to return to production by bypassing the data warehouse rebuild and restore operations.

Quick resync does not preserve the storage efficiency of the destination volumes. Enabling quick resync might increase the volume space used by the destination volumes.

This procedure assumes that the baseline in the original source volume is intact. If the baseline is not intact, you must create and initialize the relationship between the volume you are serving data from and the original source volume before performing the procedure.

For complete command syntax on commands, see the man page.

Steps

- From the original source SVM or the original source cluster, create a reverse SVM DR relationship using the same configuration, policy, and identity-preserve setting as the original SVM DR relationship:

```
snapmirror create -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example creates a relationship between the SVM from which you are serving data, `svm_backup`, and the original source SVM, `svm1`:

+

```
cluster_src::> snapmirror create -source-path svm_backup: -destination-path svm1:
```

- From the original source SVM or the original source cluster, run the following command to reverse the data protection relationship:

```
snapmirror resync -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

Although `resync` does not require a baseline transfer, it can be time-consuming. You might want to run the `resync` in off-peak hours.

+

The command fails if a common Snapshot copy does not exist on the source and destination. Use `snapmirror initialize` to reinitialize the relationship.

+

The following example reverses the relationship between the original source SVM, `svm1`, and the SVM from which you are serving data, `svm_backup`:

+

```
cluster_src::> snapmirror resync -source-path svm_backup: -destination -path svm1:
```

+

Example using `-quick-resync` option:

+

```
cluster_src::> snapmirror resync -source-path svm_backup: -destination -path svm1: -quick-resync true
```

1. When you are ready to reestablish data access to the original source SVM, stop the original destination SVM to disconnect any clients currently connected to the original destination SVM.

```
vserver stop -vserver SVM
```

The following example stops the original destination SVM which is currently serving data:

```
cluster_dst::> vserver stop svm_backup
```

2. Verify that the original destination SVM is in the stopped state by using the `vserver show` command.

```
cluster_dst::> vserver show
```

Vserver	Type	Subtype	Admin State	Operational State	Root Volume
Aggregate					
---	---	---	---	---	---
---	---	---	---	---	---
svm_backup	data	default	stopped	stopped	rv
aggr1					

3. From the original source SVM or the original source cluster, run the following command to perform the final update of the reversed relationship to transfer all changes from the original destination SVM to the original source SVM:

```
snapmirror update -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example updates the relationship between the original destination SVM from which you are serving data, `svm_backup`, and the original source SVM, `svm1`:

+

```
cluster_src::> snapmirror update -source-path svm_backup: -destination
-path svm1:
```

1. From the original source SVM or the original source cluster, run the following command to stop scheduled transfers for the reversed relationship:

```
snapmirror quiesce -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example stops scheduled transfers between the SVM you are serving data from, `svm_backup`, and the original SVM, `svm1`:

+

```
cluster_src::> snapmirror quiesce -source-path svm_backup: -destination
-path svm1:
```

1. When the final update is complete and the relationship indicates "Quiesced" for the relationship status, run the following command from the original source SVM or the original source cluster to break the reversed relationship:

```
snapmirror break -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example breaks the relationship between the original destination SVM from which you were serving data, `svm_backup`, and the original source SVM, `svm1`:

+

```
cluster_src::> snapmirror break -source-path svm_backup: -destination-path svm1:
```

1. If the original source SVM was previously stopped, from the original source cluster, start the original source SVM:

```
vserver start -vserver SVM
```

The following example starts the original source SVM:

```
cluster_src::> vserver start svm1
```

2. From the original destination SVM or the original destination cluster, reestablish the original data protection relationship:

```
snapmirror resync -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example reestablishes the relationship between the original source SVM, `svm1`, and the original destination SVM, `svm_backup`:

+

```
cluster_dst::> snapmirror resync -source-path svm1: -destination-path svm_backup:
```

1. From the original source SVM or the original source cluster, run the following command to delete the reversed data protection relationship:

```
snapmirror delete -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example deletes the reversed relationship between the original destination SVM, `svm_backup`, and the original source SVM, `svm1`:

+

```
cluster_src::> snapmirror delete -source-path svm_backup: -destination-path svm1:
```

1. From the original destination SVM or the original destination cluster, release the reversed data protection relationship:

```
snapmirror release -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example releases the reversed relationship between the original destination SVM, `svm_backup`, and the original source SVM, `svm1`.

+

```
cluster_dst::> snapmirror release -source-path svm_backup: -destination
-path svm1:
```

After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created. For complete command syntax, see the man page.

= Reactivate the original source SVM (FlexGroup volumes only)

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can reestablish the original data protection relationship between the source and destination SVM when you no longer need to serve data from the destination. To reactivate the original source SVM when you are using FlexGroup volumes, you need to perform some additional steps, including deleting the original SVM DR relationship and releasing the original relationship before you reverse the relationship. You also need to release the reversed relationship and recreate the original relationship before stopping scheduled transfers.

Steps

1. From the original destination SVM or the original destination cluster, delete the original SVM DR relationship:

```
snapmirror delete -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example deletes the original relationship between the original source SVM, svm1, and the original destination SVM, svm_backup:

+

```
cluster_dst::> snapmirror delete -source-path svm1: -destination-path  
svm_backup:
```

1. From the original source SVM or the original source cluster, release the original relationship while keeping the Snapshot copies intact:

```
snapmirror release -source-path SVM: -destination-path SVM: -relationship  
-info-only true
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example releases the original relationship between the original source SVM, svm1, and the original destination SVM, svm_backup.

+

```
cluster_src::> snapmirror release -source-path svm1: -destination-path  
svm_backup: -relationship-info-only true
```

1. From the original source SVM or the original source cluster, create a reverse SVM DR relationship using the same configuration, policy, and identity-preserve setting as the original SVM DR relationship:

```
snapmirror create -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example creates a relationship between the SVM from which you are serving data, `svm_backup`, and the original source SVM, `svm1`:

+

```
cluster_src::> snapmirror create -source-path svm_backup: -destination-path svm1:
```

1. From the original source SVM or the original source cluster, run the following command to reverse the data protection relationship:

```
snapmirror resync -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

Although `resync` does not require a baseline transfer, it can be time-consuming. You might want to run the `resync` in off-peak hours.

+

The command fails if a common Snapshot copy does not exist on the source and destination. Use `snapmirror initialize` to reinitialize the relationship.

+

The following example reverses the relationship between the original source SVM, `svm1`, and the SVM from which you are serving data, `svm_backup`:

+

```
cluster_src::> snapmirror resync -source-path svm_backup: -destination-path svm1:
```

1. When you are ready to reestablish data access to the original source SVM, stop the original destination SVM to disconnect any clients currently connected to the original destination SVM.

```
vserver stop -vserver SVM
```

The following example stops the original destination SVM which is currently serving data:

```
cluster_dst::> vserver stop svm_backup
```

2. Verify that the original destination SVM is in the stopped state by using the `vserver show` command.

```
cluster_dst::> vserver show
              Admin      Operational Root
Vserver       Type     Subtype    State      State      Volume
Aggregate
-----
-----
svm_backup    data     default    stopped   stopped    rv
aggr1
```

3. From the original source SVM or the original source cluster, run the following command to perform the final update of the reversed relationship to transfer all changes from the original destination SVM to the original source SVM:

```
snapmirror update -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example updates the relationship between the original destination SVM from which you are serving data, `svm_backup`, and the original source SVM, `svm1`:

+

```
cluster_src::> snapmirror update -source-path svm_backup: -destination-path svm1:
```

1. From the original source SVM or the original source cluster, run the following command to stop scheduled transfers for the reversed relationship:

```
snapmirror quiesce -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example stops scheduled transfers between the SVM you are serving data from, `svm_backup`, and the original SVM, `svm1`:

+

```
cluster_src::> snapmirror quiesce -source-path svm_backup: -destination-path svm1:
```

1. When the final update is complete and the relationship indicates "Quiesced" for the relationship status, run the following command from the original source SVM or the original source cluster to break the reversed relationship:

```
snapmirror break -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example breaks the relationship between the original destination SVM from which you were serving data, `svm_backup`, and the original source SVM, `svm1`:

+

```
cluster_src::> snapmirror break -source-path svm_backup: -destination
-path svm1:
```

1. If the original source SVM was previously stopped, from the original source cluster, start the original source SVM:

```
vserver start -vserver SVM
```

The following example starts the original source SVM:

```
cluster_src::> vserver start svm1
```

2. From the original source SVM or the original source cluster, delete the reversed SVM DR relationship:

```
snapmirror delete -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example deletes the reversed relationship between the original destination SVM, `svm_backup`, and the original source SVM, `svm1`:

+

```
cluster_src::> snapmirror delete -source-path svm_backup: -destination
-path svm1:
```

1. From the original destination SVM or the original destination cluster, release the reversed relationship while keeping the Snapshot copies intact:

```
snapmirror release -source-path SVM: -destination-path SVM: -relationship
-info-only true
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example releases the reversed relationship between the original destination SVM, `svm_backup`, and the original source SVM, `svm1`:

+

```
cluster_dst::> snapmirror release -source-path svm_backup: -destination-path svm1: -relationship-info-only true
```

1. From the original destination SVM or the original destination cluster, recreate the original relationship. Use the same configuration, policy, and identity-preserve setting as the original SVM DR relationship:

```
snapmirror create -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example creates a relationship between the original source SVM, `svm1`, and the original destination SVM, `svm_backup`:

+

```
cluster_dst::> snapmirror create -source-path svm1: -destination-path svm_backup:
```

1. From the original destination SVM or the original destination cluster, reestablish the original data protection relationship:

```
snapmirror resync -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example reestablishes the relationship between the original source SVM, `svm1`, and the original destination SVM, `svm_backup`:

+

```
cluster_dst::> snapmirror resync -source-path svm1: -destination-path  
svm_backup:
```

= Convert volume replication relationships to an SVM replication relationship

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can convert replication relationships between volumes to a replication relationship between the storage virtual machines (SVMs) that own the volumes, provided that each volume on the source (except the root volume) is being replicated, and each volume on the source (including the root volume) has the same name as the volume on the destination.

About this task

Use the `volume rename` command when the SnapMirror relationship is idle to rename destination volumes if necessary.

Steps

- From the destination SVM or the destination cluster, run the following command to resync the source and destination volumes:

```
snapmirror resync -source-path SVM:volume -destination-path SVM:volume  
-type DP|XDP -schedule schedule -policy policy
```

For complete command syntax, see the man page.

Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.

+

The following example resyncs the relationship between the source volume `volA` on `svm1` and the destination volume `volA` on `svm_backup`:

+

```
cluster_dst::> snapmirror resync -source-path svm1:volA -destination-path svm_backup:volA
```

1. Create an SVM replication relationship between the source and destination SVMs, as described in [Replicating SVM configurations](#).

You must use the `-identity-preserve true` option of the `snapmirror create` command when you create your replication relationship.

2. Stop the destination SVM:

```
vserver stop -vserver SVM
```

For complete command syntax, see the man page.

The following example stops the destination SVM `svm_backup`:

```
cluster_dst::> vserver stop svm_backup
```

3. From the destination SVM or the destination cluster, run the following command to resync the source and destination SVMs:

```
snapmirror resync -source-path SVM: -destination-path SVM: -type DP|XDP -schedule schedule -policy policy
```

For complete command syntax, see the man page.

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.

+

The following example resyncs the relationship between the source SVM `svm1` and the destination SVM `svm_backup`:

+

```
cluster_dst::> snapmirror resync -source-path svm1: -destination-path  
svm_backup:
```

= Delete an SVM replication relationship

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use the `snapmirror delete` and `snapmirror release` commands to delete an SVM replication relationship. You can then delete unneeded destination volumes manually.

About this task

The `snapmirror release` command deletes any SnapMirror-created Snapshot copies from the source. You can use the `-relationship-info-only` option to preserve the Snapshot copies.

For complete command syntax on commands, see the man page.

Steps

1. Run the following command from the destination SVM or the destination cluster to break the replication relationship:

```
snapmirror break -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example breaks the relationship between the source SVM `svm1` and the destination SVM `svm_backup`:

+

```
cluster_dst::> snapmirror break -source-path svm1: -destination-path  
svm_backup:
```

1. Run the following command from the destination SVM or the destination cluster to delete the replication relationship:

```
snapmirror delete -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example deletes the relationship between the source SVM `svm1` and the destination SVM `svm_backup`:

+

```
cluster_dst::> snapmirror delete -source-path svm1: -destination-path  
svm_backup:
```

1. Run the following command from the source cluster or source SVM to release the replication relationship information from the source SVM:

```
snapmirror release -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

+

The following example releases information for the specified replication relationship from the source SVM `svm1`:

+

```
cluster_src::> snapmirror release -source-path svm1: -destination-path  
svm_backup:
```

= Manage SnapMirror root volume replication

= Manage SnapMirror root volume replication overview

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/./media/

Every SVM in a NAS environment has a unique namespace. The SVM *root volume*, containing operating system and related information, is the entry point to the namespace hierarchy. To ensure that data remains accessible to clients in the event of a node outage or failover, you should create a load-sharing mirror copy of the SVM root volume.

The main purpose of load-sharing mirrors for SVM root volumes is no longer for load sharing; instead, their purpose is for disaster recovery.

- If the root volume is temporarily unavailable, the load-sharing mirror automatically provides read-only access to root volume data.
- If the root volume is permanently unavailable, you can promote one of the load-sharing volumes to provide write access to root volume data.

= Create and initializing load-sharing mirror relationships

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/./media/

You should create a load-sharing mirror (LSM) for each SVM root volume that serves NAS data in the cluster. You can create the LSM on any node other than the one containing the root volume, such as the partner node in an HA pair, or preferably in a different HA pair. For a two-node cluster, you should create the LSM on the partner of the node with the SVM root volume.

About this task

If you create an LSM on the same node, and the node is unavailable, you have a single point of failure, and you do not have a second copy to ensure the data remains accessible to clients. But when you create the LSM on a node other than the one containing the root volume, or on a different HA pair, your data is still accessible in the event of an outage.

For example, in a four-node cluster with a root volume on three nodes:

- For the root volume on HA 1 node 1, create the LSM on HA 2 node 1 or HA 2 node 2.
- For the root volume on HA 1 node 2, create the LSM on HA 2 node 1 or HA 2 node 2.
- For the root volume on HA 2 node 1, create the LSM on HA 1 node 1 or HA 1 node 2.

Steps

1. Create a destination volume for the LSM:

```
volume create -vserver SVM -volume volume -aggregate aggregate -type DP
-size size
```

The destination volume should be the same or greater in size than the root volume.

It is a best practice to name the root and destination volume with suffixes, such as `_root` and `_m1`.

For complete command syntax, see the man page.

The following example creates a load-sharing mirror volume for the root volume `svm1_root` in `cluster_src`:

```
cluster_src:> volume create -vserver svm1 -volume svm1_m1 -aggregate
aggr_1 -size 1gb -state online -type DP
```

2. Create a replication job schedule, as described in [Creating a replication job schedule](#).
3. Create a load-sharing mirror relationship between the SVM root volume and the destination volume for the LSM:

```
snapmirror create -source-path SVM:volume|cluster://SVM/volume -destination
-path SVM:volume|cluster://SVM/volume -type LS -schedule schedule
```

For complete command syntax, see the man page.

The following example creates a load-sharing mirror relationship between the root volume `svm1_root` and the load-sharing mirror volume `svm1_m1`:

```
cluster_src:> snapmirror create -source-path svm1:svm1_root
-destination-path svm1:svm1_m1 -type LS -schedule hourly
```

The type attribute of the load-sharing mirror changes from `DP` to `LS`.

4. Initialize the load-sharing mirror:

```
snapmirror initialize-ls-set -source-path SVM:volume|cluster://SVM/volume
```

Initialization can be time-consuming. You might want to run the baseline transfer in off-peak hours.

For complete command syntax, see the man page.

The following example initializes the load-sharing mirror for the root volume `svm1_root`:

```
cluster_src::> snapmirror initialize-ls-set -source-path  
svm1:svm1_root
```

= Update a load-sharing mirror relationship
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

Load-sharing mirror (LSM) relationships are updated automatically for SVM root volumes after a volume in the SVM is mounted or unmounted, and during `volume create` operations that include the `junction-path` option. You can manually update a LSM relationship if you want it updated before the next scheduled update.

Load-sharing mirror relationships update automatically in the following circumstances:

- It's time for a scheduled update
- A mount or unmount operation is performed on a volume in the SVM root volume
- A `volume create` command is issued that includes the `juntion-path` option

Step

1. Update a load-sharing mirror relationship manually:

```
snapmirror update-ls-set -source-path SVM:volume|cluster://SVM/volume
```

The following example updates the load-sharing mirror relationship for the root volume `svm1_root`:

```
cluster_src::> snapmirror update-ls-set -source-path svm1:svm1_root
```

= Promote a load-sharing mirror
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

If a root volume is permanently unavailable, you can promote the load-sharing mirror (LSM) volume to provide write access to root volume data.

What you'll need

You must use advanced privilege level commands for this task.

Steps

1. Change to advanced privilege level:

```
set -privilege advanced
```

2. Promote an LSM volume:

```
snapmirror promote -destination-path SVM:volume|cluster://SVM/volume
```

For complete command syntax, see the man page.

The following example promotes the volume `svm1_m2` as the new SVM root volume:

```
cluster_src::*> snapmirror promote -destination-path svm1:svm1_m2

Warning: Promote will delete the offline read-write volume
cluster_src://svm1/svm1_root and replace it with
cluster_src://svm1/svm1_m2. Because the volume is offline,
it is not possible to determine whether this promote will
affect other relationships associated with this source.

Do you want to continue? {y|n}: y
```

Enter `y`. ONTAP makes the LSM volume a read/write volume, and deletes the original root volume if it is accessible.

The promoted root volume might not have all of the data that was in the original root volume if the last update did not occur recently.

1. Return to admin privilege level:

```
set -privilege admin
```

2. Rename the promoted volume following the naming convention you used for the root volume:

```
volume rename -vserver SVM -volume volume -newname new_name
```

The following example renames the promoted volume `svm1_m2` with the name `svm1_root`:

```
cluster_src::> volume rename -vserver svm11 -volume svm1_m2 -newname  
svm1_root
```

3. Protect the renamed root volume, as described in step 3 through step 4 in [Creating and initializing load-sharing mirror relationships](#).

= SnapMirror technical details

= Use path name pattern matching

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use pattern matching to specify the source and destination paths in `snapmirror` commands.

`snapmirror` commands use fully qualified path names in the following format: `vserver:volume`. You can abbreviate the path name by not entering the SVM name. If you do this, the `snapmirror` command assumes the local SVM context of the user.

Assuming that the SVM is called “`vserver1`” and the volume is called “`vol1`”, the fully qualified path name is `vserver1:vol1`.

You can use the asterisk (*) in paths as a wildcard to select matching, fully qualified path names. The following table provides examples of using the wildcard to select a range of volumes.

*	Matches all paths.
vs*	Matches all SVMs and volumes with SVM names beginning with <code>vs</code> .
:*src	Matches all SVMs with volume names containing the <code>src</code> text.
:vol	Matches all SVMs with volume names beginning with <code>vol</code> .

```

vs1::> snapmirror show -destination-path *:*dest*
Progress
Source           Destination   Mirror      Relationship  Total
Last
Path            Type    Path        State       Status      Progress
Healthy Updated
-----
----- vs1:sm_src2
          DP     vs2:sm_dest1
                           Snapmirrored  Idle
true      -

```

= Use extended queries to act on many SnapMirror relationships

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use *extended queries* to perform SnapMirror operations on many SnapMirror relationships at one time. For example, you might have multiple uninitialized SnapMirror relationships that you want to initialize using one command.

About this task

You can apply extended queries to the following SnapMirror operations:

- Initializing uninitialized relationships
- Resuming quiesced relationships
- Resynchronizing broken relationships
- Updating idle relationships
- Aborting relationship data transfers

Step

1. Perform a SnapMirror operation on many relationships:

```
snapmirror command {-state state} *
```

The following command initializes SnapMirror relationships that are in an Uninitialized state:

```
vs1::> snapmirror initialize {-state Uninitialized} *
```

= Ensure a common Snapshot copy in a mirror-vault deployment

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use the `snapmirror snapshot-owner create` command to preserve a labeled Snapshot copy on the secondary in a mirror-vault deployment. Doing so ensures that a common Snapshot copy exists for the update of the vault relationship.

About this task

If you use a combination mirror-vault fan-out or cascade deployment, you should keep in mind that updates will fail if a common Snapshot copy does not exist on the source and destination volumes.

This is never an issue for the mirror relationship in a mirror-vault fan-out or cascade deployment, since SnapMirror always creates a Snapshot copy of the source volume before it performs the update.

It might be an issue for the vault relationship, however, since SnapMirror does not create a Snapshot copy of the source volume when it updates a vault relationship. You need to use the `snapmirror snapshot-owner create` to ensure that there is at least one common Snapshot copy on both the source and destination of the vault relationship.

Steps

1. On the source volume, assign an owner to the labeled Snapshot copy you want to preserve:

```
snapmirror snapshot-owner create -vserver SVM -volume volume -snapshot  
snapshot -owner owner
```

The following example assigns ApplicationA as the owner of the `snap1` Snapshot copy:

```
clust1::> snapmirror snapshot-owner create -vserver vs1 -volume vol1  
-snapshot snap1 -owner ApplicationA
```

2. Update the mirror relationship, as described in [Updating a replication relationship manually](#).

Alternatively, you can wait for the scheduled update of the mirror relationship.

3. Transfer the labeled Snapshot copy to the vault destination:

```
snapmirror update -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ... -source-snapshot  
snapshot
```

For complete command syntax, see the man page.

The following example transfers the `snap1` Snapshot copy

```
clust1::> snapmirror update -vserver vs1 -volume vol1  
-source-snapshot snap1
```

The labeled Snapshot copy will be preserved when the vault relationship is updated.

4. On the source volume, remove the owner from the labeled Snapshot copy:

```
snapmirror snapshot-owner delete -vserver SVM -volume volume -snapshot  
snapshot -owner owner
```

The following examples removes ApplicationA as the owner of the snap1 Snapshot copy:

```
clust1::> snapmirror snapshot-owner delete -vserver vs1 -volume vol1  
-snapshot snap1 -owner ApplicationA
```

= Compatible ONTAP versions for SnapMirror relationships

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You should verify that the source and destination volumes are running compatible ONTAP versions before creating a SnapMirror data protection relationship.

Version-independence is not supported for SVM replication.

== Unified replication relationships

For SnapMirror relationships of type “XDP”, using on premises or Cloud Volumes ONTAP releases:

Beginning with ONTAP 9.9.0:

- ONTAP 9.x.0 releases are cloud-only releases and support Cloud Volumes ONTAP (CVO) systems. The asterisk (*) after the release version indicates a cloud-only release.
- ONTAP 9.x.1 releases are general releases and support both on-premises and CVO systems.

Locate the higher, more recent ONTAP version in the left column, and in the top row locate the lower ONTAP version to determine interoperability. Interoperability is bidirectional.

Interoperability for ONTAP version 9.3 and later

ONT AP vers ion ...	Interoperates with these previous ONTAP versions...																	
	9.13. 1	9.13. 0*	9.12. 1	9.12. 0*	9.11. 1	9.11. 0*	9.10. 1	9.10. 0*	9.9.1 *	9.9.0	9.8	9.7	9.6	9.5	9.4	9.3

-- SnapMirror SVM DR relationships

For SVM DR data and SVM protection:

SVM DR is only supported between clusters running the same version of ONTAP.

For SVM DR for SVM migration:

- Replication is supported in a single direction from an earlier version of ONTAP to a later version of ONTAP; for example, from ONTAP 9.11.1 to ONTAP 9.12.
- The ONTAP version on the target cluster must be no more than 2 versions newer, as shown in the table below.
- Replication is not supported for long-term data protection use cases.

The asterisk (*) after the release version indicates a cloud-only release.

Source	Destination															
	9.3	9.4	9.5	9.6	9.7	9.8	9.9.0*	9.9.1	9.10.0*	9.10.1	9.11.0*	9.11.1	9.12.0*	9.12.1	9.13.0*	9.13.1
9.3	Yes	Yes	Yes													
9.4		Yes	Yes	Yes												
9.5			Yes	Yes	Yes											
9.6				Yes	Yes	Yes										
9.7					Yes	Yes	Yes

9.10. 1						Yes	Yes	Yes					
9.11. 0*						Yes	Yes	Yes					
9.11. 1						Yes	Yes	Yes					
9.12. 0*						Yes	Yes	Yes					
9.12. 1						Yes	Yes	Yes					
9.13. 0*						Yes	Yes	Yes					
9.13. 1						Yes	Yes	Yes					

== SnapMirror DR relationships

For SnapMirror relationships of type “DP” and policy type “async-mirror”:

DP-type mirrors cannot be initialized beginning with ONTAP 9.11.1 and are completely deprecated in ONTAP 9.12.1. For more information, see [Deprecation of data protection SnapMirror relationships](#).

In the following table, the column on the left indicates the ONTAP version on the source volume, and the top row indicates the ONTAP versions you can have on your destination volume.

Source	Destination												
	9.11.1	9.10.1	9.9.1	9.8	9.7	9.6	9.5	9.4	9.3	9.2	9.1	9	
9.11.1	Yes	No	No	No	No	No	No	No	No	No	No	No	No
9.10.1	Yes	Yes	No	No	No	No	No	No	No	No	No	No	No
9.9.1	Yes	Yes	Yes	No									
9.8	No	Yes	Yes	Yes	No								
9.7	No	No	Yes	Yes	Yes	No

9	No	No	No	No	No	No	No	No	No	Yes	Yes	Yes	Yes

Interoperability is not bidirectional.

= SnapMirror limitations

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You should be aware of basic SnapMirror limitations before creating a data protection relationship.

- A destination volume can have only one source volume.

A source volume can have multiple destination volumes. The destination volume can be the source volume for any type of SnapMirror replication relationship.

- You can fan out a maximum of eight destination volumes from a single source volume.
- You cannot restore files to the destination of a SnapMirror DR relationship.
- Source or destination SnapVault volumes cannot be 32-bit.
- The source volume for a SnapVault relationship should not be a FlexClone volume.

The relationship will work, but the efficiency offered by FlexClone volumes will not be preserved.

= Archive and compliance using SnapLock technology

= What SnapLock is

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

SnapLock is a high-performance compliance solution for organizations that use WORM storage to retain files in unmodified form for regulatory and governance purposes.

SnapLock helps to prevent deletion, change, or renaming of data to meet regulations such as SEC 17a-4, HIPAA, FINRA, CFTC, and GDPR. With SnapLock, you can create special-purpose volumes in which files can be stored and committed to a non-erasable, non-writable state either for a designated retention period or indefinitely. SnapLock allows this retention to be performed at the file level through standard open file protocols such as CIFS and NFS. The supported open file protocols for SnapLock are NFS (versions 2, 3, and 4) and CIFS (SMB 1.0, 2.0, and 3.0).

Using SnapLock, you commit files and Snapshot copies to WORM storage, and set retention periods for WORM-protected data. SnapLock WORM storage uses NetApp Snapshot technology and can leverage SnapMirror replication, and SnapVault backups as the base technology for providing backup recovery protection for data.

Learn more about WORM storage: [Compliant WORM storage using NetApp SnapLock - TR-4526](#).

You can use an application to commit files to WORM over NFS or CIFS, or use the SnapLock autocommit feature to commit files to WORM automatically. You can use a *WORM appendable file* to retain data that is written incrementally, like log information. For more information see [Use volume append mode to create WORM appendable files](#).

SnapLock supports data protection methods that should satisfy most compliance requirements:

- You can use SnapLock for SnapVault to WORM-protect Snapshot copies on secondary storage. See [Commit Snapshot copies to WORM](#).
- You can use SnapMirror to replicate WORM files to another geographic location for disaster recovery. See [Mirror WORM files](#).

SnapLock is a license-based feature of NetApp ONTAP. A single license entitles you to use SnapLock in strict Compliance mode, to satisfy external mandates like SEC Rule 17a-4, and a looser Enterprise mode, to meet internally mandated regulations for the protection of digital assets. SnapLock licenses are part of the Security and Compliance bundle.

SnapLock is supported on all AFF and FAS systems as well as ONTAP Select. SnapLock is not a software-only solution; it is an integrated hardware and software solution. This distinction is important for strict WORM regulations such as SEC 17a-4, which requires an integrated hardware and software solution. For more information, refer to [SEC Interpretation: Electronic Storage of Broker-Dealer Records](#).

== What you can do with SnapLock

After you configure SnapLock, you can complete the following tasks:

- [Commit files to WORM](#)
- [Commit Snapshot copies to WORM for secondary storage](#)

- Mirror WORM files for disaster recovery
- Retain WORM files during litigation using Legal Hold
- Delete WORM files using the privileged delete feature
- Set the file retention period
- Move a SnapLock volume
- Lock a Snapshot copy for protection against ransomware attacks
- Review SnapLock use with the Audit Log
- Use SnapLock APIs

== SnapLock Compliance and Enterprise modes

SnapLock Compliance and Enterprise modes differ mainly in the level at which each mode protects WORM files:

SnapLock mode	Protection level	WORM file deleting during retention
Compliance mode	At the file level	Cannot be deleted
Enterprise mode	At the disk level	Can be deleted by the compliance administrator using an audited “privileged delete” procedure

After the retention period has elapsed, you are responsible for deleting any files you no longer need. Once a file has been committed to WORM, whether under Compliance or Enterprise mode, it cannot be modified, even after the retention period has expired.

You cannot move a WORM file during or after the retention period. You can copy a WORM file, but the copy will not retain its WORM characteristics.

The following table shows the differences in capabilities supported by SnapLock Compliance and Enterprise modes:

Capability	SnapLock Compliance	SnapLock Enterprise
Enable and delete files using privileged delete	No	Yes
Reinitialize disks	No	Yes
Destroy SnapLock aggregates and volumes during retention period	No	Yes, with the exception of the SnapLock audit log volume
Rename aggregates or volumes	No	Yes
Use non-NetApp disks	No	Yes (with FlexArray Virtualization)

Use the SnapLock volume for audit logging	Yes	Yes, beginning with ONTAP 9.5
---	-----	-------------------------------

== Supported and unsupported features with SnapLock

The following table shows the features that are supported with SnapLock Compliance mode, SnapLock Enterprise mode, or both:

Feature	Supported with SnapLock Compliance	Supported with SnapLock Enterprise
Consistency Groups	No	No
Encrypted volumes	Yes, beginning with ONTAP 9.2. Learn more about Encryption and SnapLock .	Yes, beginning with ONTAP 9.2. Learn more about Encryption and SnapLock .
FabricPools on SnapLock aggregates	No	Yes, beginning with ONTAP 9.8. Learn more about FabricPool on SnapLock Enterprise aggregates .
Flash Pool aggregates	Yes, beginning with ONTAP 9.1.	Yes, beginning with ONTAP 9.1.
FlexClone	You can clone SnapLock volumes, but you cannot clone files on a SnapLock volume.	You can clone SnapLock volumes, but you cannot clone files on a SnapLock volume.
FlexGroup volumes	Yes, beginning with ONTAP 9.11.1. Learn more about [flexgroup] .	Yes, beginning with ONTAP 9.11.1. Learn more about [flexgroup] .
LUNs	No	No
MetroCluster configurations	Yes, beginning with ONTAP 9.3. Learn more about MetroCluster support .	Yes, beginning with ONTAP 9.3. Learn more about MetroCluster support .
Multi-admin verification (MAV)	Yes, beginning with ONTAP 9.13.1. Learn more about MAV support .	Yes, beginning with ONTAP 9.13.1. Learn more about MAV support .
SAN	No	No
Single-file SnapRestore	No	Yes
SnapMirror Business Continuity	No	No

SnapRestore	No	Yes
SMTape	No	No
SnapMirror Synchronous	No	No
SSDs	Yes, beginning with ONTAP 9.1.	Yes, beginning with ONTAP 9.1.
Storage efficiency features	Yes, beginning with ONTAP 9.9.1. Learn more about storage efficiency support .	Yes, beginning with ONTAP 9.9.1. Learn more about storage efficiency support .

== FabricPool on SnapLock Enterprise aggregates

FabricPools are supported on SnapLock Enterprise aggregates beginning with ONTAP 9.8. However, your account team needs to open a product variance request documenting that you understand that FabricPool data tiered to a public or private cloud is no longer protected by SnapLock because a cloud admin can delete that data.

Any data that FabricPool tiers to a public or private cloud is no longer protected by SnapLock because that data can be deleted by a cloud administrator.

== FlexGroup volumes

SnapLock supports FlexGroup volumes beginning with ONTAP 9.11.1; however, the following features are not supported:

- Legal-hold
- Event-based retention
- SnapLock for SnapVault (supported beginning with ONTAP 9.12.1)

You should also be aware of the following behaviors:

- The volume compliance clock (VCC) of a FlexGroup volume is determined by the VCC of the root constituent. All non-root constituents will have their VCC closely synced to the root VCC.
- SnapLock configuration properties are set only on the FlexGroup as a whole. Individual constituents cannot have different configuration properties, such as default retention time and autocommit period.

== MetroCluster support

SnapLock support in MetroCluster configurations differs between SnapLock Compliance mode and SnapLock Enterprise mode.

SnapLock Compliance

- Beginning with ONTAP 9.3, SnapLock Compliance is supported on unmirrored MetroCluster aggregates.
- Beginning with ONTAP 9.3, SnapLock Compliance is supported on mirrored aggregates, but only if the aggregate is used to host SnapLock audit log volumes.
- SVM-specific SnapLock configurations can be replicated to primary and secondary sites using MetroCluster.

SnapLock Enterprise

- Beginning with ONTAP 9, SnapLock Enterprise aggregates are supported.
- Beginning with ONTAP 9.3, SnapLock Enterprise aggregates with privileged delete are supported.
- SVM-specific SnapLock configurations can be replicated to both sites using MetroCluster.

MetroCluster configurations and compliance clocks

MetroCluster configurations use two compliance clock mechanisms, the Volume Compliance Clock (VCC) and the System Compliance Clock (SCC). The VCC and SCC are available to all SnapLock configurations. When you create a new volume on a node, its VCC is initialized with the current value of the SCC on that node. After the volume is created, the volume and file retention time is always tracked with the VCC.

When a volume is replicated to another site, its VCC is also replicated. When a volume switchover occurs, from Site A to Site B, for example, the VCC continues to be updated on Site B while the SCC on Site A halts when Site A goes offline.

When Site A is brought back online and the volume switchback is performed, the Site A SCC clock restarts while the VCC of the volume continues to be updated. Because the VCC is continuously updated, regardless of switchover and switchback operations, the file retention times do not depend on SCC clocks and do not stretch.

== Multi-admin verification (MAV) support

Beginning with ONTAP 9.13.1, a cluster administrator can explicitly enable multi-admin verification on a cluster to require quorum approval before some SnapLock operations are executed. When MAV is enabled, SnapLock volume properties such as default-retention-time, minimum-retention-time, maximum-retention-time, volume-append-mode, autocommit-period and privileged-delete will require quorum approval. Learn more about [MAV](#).

== Storage efficiency

Beginning with ONTAP 9.9.1, SnapLock supports storage efficiency features, such as data compaction, cross-volume-deduplication, and adaptive compression for SnapLock volumes and aggregates. For more information about storage efficiency, see [Logical storage management overview with the CLI](#).

== Encryption

ONTAP offers both software- and hardware-based encryption technologies for ensuring that data at rest cannot be read if the storage medium is repurposed, returned, misplaced, or stolen.

Disclaimer: NetApp cannot guarantee that SnapLock-protected WORM files on self-encrypting drives or volumes will be retrievable if the authentication key is lost or if the number of failed authentication attempts exceeds the specified limit and results in the drive being permanently locked. You are responsible for ensuring against authentication failures.

Beginning with ONTAP 9.2, encrypted volumes are supported on SnapLock aggregates.

== 7-Mode Transition

You can migrate SnapLock volumes from 7-Mode to ONTAP by using the Copy-Based Transition (CBT) feature of the 7-Mode Transition Tool. The SnapLock mode of the destination volume, Compliance or Enterprise, must match the SnapLock mode of the source volume. You cannot use Copy-Free Transition (CFT) to migrate SnapLock volumes.

= Configure SnapLock

= Configure SnapLock

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

Before you use SnapLock, you need to configure SnapLock by completing various tasks such as install the SnapLock license, initialize Compliance Clock, create a SnapLock aggregate and more.

= Install the license

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

A SnapLock license entitles you to use both SnapLock Compliance mode and SnapLock Enterprise mode. SnapLock licenses are issued on a per-node basis. You must install a license for each node that hosts a SnapLock aggregate.

For details about Compliance mode and Enterprise mode, see [What SnapLock is](#).

What you'll need

You must be a cluster administrator to perform this task.

About this task

You should have received the SnapLock license keys from your sales representative.

Perform this task using ONTAP System Manager or the ONTAP CLI.

1. Navigate to **Cluster > Settings > Licenses > Add License**.

2. Click **+Add**.

3. Click **Browse** and locate the NetApp License File.

4. Click **Add**.

1. Install the SnapLock license for a node:

```
system license add -license-code license_key
```

The following command installs the license with the key AAAAAAAAAAAAAAAAAAAAAA.

```
cluster1::> system license add -license-code  
AAAAAAAAAAAAAAAAAAAAAA
```

2. Repeat the previous step for each node license.

```
= Initialize the ComplianceClock  
:icons: font  
:relative_path: ./snaplock/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/
```

The SnapLock *ComplianceClock* ensures against tampering that might alter the retention period for WORM files. You must initialize the *system ComplianceClock* on each node that hosts a SnapLock aggregate. Once you initialize the *ComplianceClock* on a node, you cannot initialize it again.

What you'll need

- You must be a cluster administrator to perform this task.
- The SnapLock license must be installed on the node.

About this task

The time on the *system ComplianceClock* is inherited by the *volume ComplianceClock*, which controls the retention period for WORM files on the volume. The *volume ComplianceClock* is initialized automatically when you create a new SnapLock volume.

The initial setting of the *ComplianceClock* is based on the current system clock. For that reason, you should verify that the system time and time zone are correct before initializing the *ComplianceClock*. Once you initialize the *ComplianceClock* on a node, you cannot initialize it again.

Beginning with ONTAP 9.12.1, you can use System Manager to initialize the SnapLock *Compliance Clock*.

Steps

1. Navigate to **Cluster > Overview**.
2. In the **Nodes** section, click **Initialize SnapLock Compliance Clock**.
3. To display the *Compliance Clock* column and to verify that the *Compliance Clock* is initialized, in the **Cluster > Overview > Nodes** section, click **Show/Hide** and select **SnapLock Compliance Clock**.

CLI

1. Initialize the *system ComplianceClock*:

```
snaplock compliance-clock initialize -node node_name
```

The following command initializes the *system ComplianceClock* on *node1*:

```
cluster1::> snaplock compliance-clock initialize -node node1
```

- When prompted, confirm that the system clock is correct and that you want to initialize the ComplianceClock:

```
Warning: You are about to initialize the secure ComplianceClock of  
the node "node1" to the current value of the node's system clock.  
This procedure can be performed only once on a given node, so you  
should ensure that the system time is set correctly before proceeding.
```

```
The current node's system clock is: Mon Apr 25 06:04:10 GMT 2016
```

```
Do you want to continue? (y|n): y
```

- Repeat this procedure for each node that hosts a SnapLock aggregate.

== Enable ComplianceClock resynchronization for an NTP-configured system

You can enable the SnapLock ComplianceClock time synchronization feature when an NTP server is configured.

What you'll need

- This feature is available only at the advanced privilege level.
- You must be a cluster administrator to perform this task.
- The SnapLock license must be installed on the node.
- This feature is available only for Cloud Volumes ONTAP, ONTAP Select, and VSIM platforms.

About this task

When the SnapLock secure clock daemon detects a skew beyond the threshold, ONTAP uses the system time to reset both the system and volume ComplianceClocks. A period of 24 hours is set as the skew threshold. This means that the system ComplianceClock is synchronized to the system clock only if the skew is more than a day old.

The SnapLock secure clock daemon detects a skew and changes the ComplianceClock to the system time. Any attempt at modifying the system time to force the ComplianceClock to synchronize to the system time fails, since the ComplianceClock synchronizes to the system time only if the system time is synchronized with the NTP time.

Steps

1. Enable the SnapLock ComplianceClock time synchronization feature when an NTP server is configured:

```
snaplock compliance-clock ntp
```

The following command enables the system ComplianceClock time synchronization feature:

```
cluster1::>*> snaplock compliance-clock ntp modify -is-sync-enabled  
true
```

2. When prompted, confirm that the configured NTP servers are trusted and that the communications channel is secure to enable the feature:
3. Check that the feature is enabled:

```
snaplock compliance-clock ntp show
```

The following command checks that the system ComplianceClock time synchronization feature is enabled:

```
cluster1::>*> snaplock compliance-clock ntp show
```

```
Enable clock sync to NTP system time: true
```

= Create a SnapLock aggregate

```
:icons: font
:relative_path: ./snaplock/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/
```

You use the volume –snaplock-type option to specify a Compliance or Enterprise SnapLock volume type. For releases earlier than ONTAP 9.10.1, you must create a separate SnapLock aggregate. Beginning with ONTAP 9.10.1, SnapLock and non-SnapLock volumes can exist on the same aggregate; therefore, you are no longer required to create a separate SnapLock aggregate if you are using ONTAP 9.10.1.

What you'll need

- You must be a cluster administrator to perform this task.
- The SnapLock license must be installed on the node.
- The ComplianceClock on the node must be initialized.
- If you have partitioned the disks as “root”, “data1”, and “data2”, you must ensure that spare disks are available.

Upgrade considerations

When upgrading to ONTAP 9.10.1, existing SnapLock and non-SnapLock aggregates are upgraded to support the existence of both SnapLock and non-SnapLock volumes; however, the existing SnapLock volume attributes are not automatically updated. For example, data-compaction, cross-volume-dedupe, and cross-volume-background-dedupe fields remain unchanged. New SnapLock volumes created on existing aggregates have the same default values as non-SnapLock volumes, and the default values for new volumes and aggregates are platform dependent.

Revert considerations

If you need to revert to an ONTAP version earlier than 9.10.1, you must move all SnapLock Compliance, SnapLock Enterprise, and SnapLock volumes to their own SnapLock aggregates.

About this task

- You cannot create Compliance aggregates for FlexArray LUNs, but SnapLock Compliance aggregates are supported with FlexArray LUNs.
- You cannot create Compliance aggregates with the SyncMirror option.
- You can create mirrored Compliance aggregates in a MetroCluster configuration only if the aggregate is used to host SnapLock audit log volumes.

In a MetroCluster configuration, SnapLock Enterprise is supported on mirrored and unmirrored aggregates. SnapLock Compliance is supported only on unmirrored aggregates.

Steps

1. Create a SnapLock aggregate:

```
storage aggregate create -aggregate aggregate_name -node node_name  
-diskcount number_of_disks -snaplock-type compliance|enterprise
```

The man page for the command contains a complete list of options.

The following command creates a SnapLock Compliance aggregate named aggr1 with three disks on node1:

```
cluster1::> storage aggregate create -aggregate aggr1 -node node1  
-diskcount 3 -snaplock-type compliance
```

= Create and mount SnapLock volumes

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You must create a SnapLock volume for the files or Snapshot copies that you want to commit to the WORM state. Beginning with ONTAP 9.10.1, any volume you create, regardless of the aggregate type, is created by default as a non-SnapLock volume. You must use the `-snaplock-type` option to explicitly create a SnapLock volume by specifying either Compliance or Enterprise as the SnapLock type. By default, the SnapLock type is set to non-snaplock.

What you'll need

- The SnapLock aggregate must be online.
- The SnapLock license must be installed on the node.
- The ComplianceClock on the node must be initialized.

About this task

With the proper SnapLock permissions, you can destroy or rename an Enterprise volume at any time. You cannot destroy a Compliance volume until the retention period has elapsed. You can never rename a Compliance volume.

You can clone SnapLock volumes, but you cannot clone files on a SnapLock volume. The clone volume will be of the same SnapLock type as the parent volume.

LUNs are not supported on SnapLock volumes. Although it is possible to move LUNs onto a SnapLock volume using legacy technology, this is not a supported operation, nor is any other operation involving LUNs on a SnapLock volume.

Perform this task using ONTAP System Manager or the ONTAP CLI.

Beginning with ONTAP 9.12.1, you can use System Manager to create a SnapLock volume.

Steps

1. Navigate to **Storage > Volumes** and click **Add**.
2. In the **Add Volume** window, click **More Options**.
3. Enter the new volume information, including the name and size of the volume.
4. Select **Enable SnapLock** and choose the SnapLock type, either Compliance or Enterprise.
5. In the **Auto-Commit Files** section, select **Modified** and enter the amount of time a file should remain unchanged before it is automatically committed. The minimum value is 5 minutes and the maximum value is 10 years.
6. In the **Data Retention** section, select the minimum and maximum retention period.
7. Select the default retention period.
8. Click **Save**.
9. Select the new volume in the **Volumes** page to verify the SnapLock settings.

1. Create a SnapLock volume:

```
volume create -vserver SVM_name -volume volume_name -aggregate aggregate_name  
-snaplock-type compliance|enterprise
```

For a complete list of options, see the man page for the command. The following options are not available for SnapLock volumes: `-nvfail`, `-atime-update`, `-is-autobalance-eligible`, `-space-mgmt`, `-try-first`, and `valign`.

The following command creates a SnapLock Compliance volume named `vol1` on `aggr1` on `vs1`:

```
cluster1::> volume create -vserver vs1 -volume vol1 -aggregate aggr1  
-snaplock-type compliance
```

== Mount a SnapLock volume

You can mount a SnapLock volume to a junction path in the SVM namespace for NAS client access.

What you'll need

The SnapLock volume must be online.

About this task

- You can mount a SnapLock volume only under the root of the SVM.
- You cannot mount a regular volume under a SnapLock volume.

Steps

1. Mount a SnapLock volume:

```
volume mount -vserver SVM_name -volume volume_name -junction-path path
```

For a complete list of options, see the man page for the command.

The following command mounts a SnapLock volume named `vol1` to the junction path `/sales` in the `vs1` namespace:

```
cluster1::> volume mount -vserver vs1 -volume vol1 -junction-path  
/sales
```

= Set the retention time

:icons: font

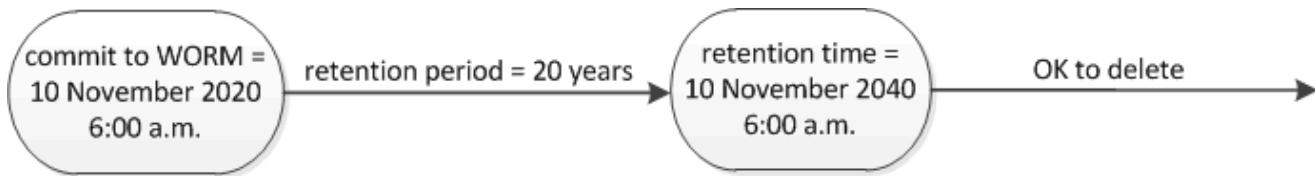

:relative_path: ./snaplock/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can set the retention time for a file explicitly, or you can use the default retention period for the volume to derive the retention time. Unless you set the retention time explicitly, SnapLock uses the default retention period to calculate the retention time. You can also set file retention after an event.

About retention period and retention time

The *retention period* for a WORM file specifies the length of time the file must be retained after it is committed to the WORM state. The *retention time* for a WORM file is the time after which the file no longer needs to be retained. A retention period of 20 years for a file committed to the WORM state on 10 November 2020 6:00 a.m., for example, would yield a retention time of 10 November 2040 6:00 a.m.

Beginning with ONTAP 9.10.1, you can set a retention time up to October 26, 3058 and a retention period up to 100 years. When you extend retention dates, older policies are converted automatically. In ONTAP 9.9.1 and

earlier releases, unless you set the default retention period to infinite, the maximum supported retention time is January 19 2071 (GMT).

Important replication considerations

When establishing a SnapMirror relationship with a SnapLock source volume using a retention date later than January 19th 2071 (GMT), the destination cluster must be running ONTAP 9.10.1 or later or the SnapMirror transfer will fail.

Important revert considerations

ONTAP prevents you from reverting a cluster from ONTAP 9.10.1 to an earlier ONTAP version when there are any files with a retention period later than “January 19, 2071 8:44:07 AM”.

Understanding the default retention periods

A SnapLock Compliance or Enterprise volume has four retention periods:

- Minimum retention period (`min`), with a default of 0
- Maximum retention period (`max`), with a default of 30 years
- Default retention period, with a default equal to `min` for both Compliance mode and Enterprise mode beginning with ONTAP 9.10.1. In ONTAP releases earlier than ONTAP 9.10.1, the default retention period depends on the mode:
 - For Compliance mode, the default is equal to `max`.
 - For Enterprise mode, the default is equal to `min`.
- Unspecified retention period.

Beginning with ONTAP 9.8, you can set the retention period on files in a volume to `unspecified`, to enable the file to be retained until you set an absolute retention time. You can set a file with absolute retention time to unspecified retention and back to absolute retention as long as the new absolute retention time is later than the absolute time you previously set.

Beginning with ONTAP 9.12.1, WORM files with the retention period set to `unspecified` are guaranteed to have a retention period set to the minimum retention period configured for the SnapLock volume. When you change the file retention period from `unspecified` to an absolute retention time, the new retention time specified must be greater than the minimum retention time already set on the file.

So, if you do not set the retention time explicitly before committing a Compliance-mode file to the WORM state, and you do not modify the defaults, the file will be retained for 30 years. Similarly, if you do not set the retention time explicitly before committing an Enterprise-mode file to the WORM state, and you do not modify the defaults, the file will be retained for 0 years, or, effectively, not at all.

== Set the default retention period

You can use the `volume snaplock modify` command to set the default retention period for files on a SnapLock volume.

What you'll need

The SnapLock volume must be online.

About this task

The following table shows the possible values for the default retention period option:

The default retention period must be greater than or equal to (\geq) the minimum retention period and less than or equal to (\leq) the maximum retention period.

Value	Unit	Notes
0 - 65535	seconds	
0 - 24	hours	
0 - 365	days	
0 - 12	months	
0 - 100	years	Beginning with ONTAP 9.10.1. For earlier ONTAP releases, the value is 0 - 70.
max	-	Use the maximum retention period.
min	-	Use the minimum retention period.
infinite	-	Retain the files forever.
unspecified	-	Retain the files until an absolute retention period is set.

The values and ranges for the maximum and minimum retention periods are identical, except for `max` and `min`, which are not applicable. For more information about this task, see [Set the retention time overview](#).

You can use the `volume snaplock show` command to view the retention period settings for the volume. For more information, see the man page for the command.

After a file has been committed to the WORM state, you can extend but not shorten the retention period.

Steps

1. Set the default retention period for files on a SnapLock volume:

```
volume snaplock modify -vserver SVM_name -volume volume_name -default
-retention-period default_retention_period -minimum-retention-period
min_retention_period -maximum-retention-period max_retention_period
```

For a complete list of options, see the man page for the command.

The following examples assume that the minimum and maximum retention periods have not been modified

previously.

+

The following command sets the default retention period for a Compliance or Enterprise volume to 20 days:

+

```
cluster1::> volume snaplock modify -vserver vs1 -volume vol1 -default  
-retention-period 20days
```

+

The following command sets the default retention period for a Compliance volume to 70 years:

+

```
cluster1::> volume snaplock modify -vserver vs1 -volume vol1 -maximum  
-retention-period 70years
```

+

The following command sets the default retention period for an Enterprise volume to 10 years:

+

```
cluster1::> volume snaplock modify -vserver vs1 -volume vol1 -default  
-retention-period max -maximum-retention-period 10years
```

+

The following commands set the default retention period for an Enterprise volume to 10 days:

+

```
cluster1::> volume snaplock modify -vserver vs1 -volume vol1 -minimum  
-retention-period 10days  
cluster1::> volume snaplock modify -vserver vs1 -volume vol1 -default  
-retention-period min
```

+

The following command sets the default retention period for a Compliance volume to infinite:

+

```
cluster1::> volume snaplock modify -vserver vs1 -volume vol1 -default  
-retention-period infinite -maximum-retention-period infinite
```

== Set the retention time for a file explicitly

You can set the retention time for a file explicitly by modifying its last access time. You can use any suitable command or program over NFS or CIFS to modify the last access time.

About this task

After a file has been committed to WORM, you can extend but not shorten the retention time. The retention time is stored in the `atime` field for the file.

You cannot explicitly set the retention time of a file to `infinite`. That value is only available when you use the default retention period to calculate the retention time.

Steps

1. Use a suitable command or program to modify the last access time for the file whose retention time you want to set.

In a UNIX shell, use the following command to set a retention time of 21 November 2020 6:00 a.m. on a file named `document.txt`:

```
touch -a -t 202011210600 document.txt
```

You can use any suitable command or program to modify the last access time in Windows.

-- Set the file retention period after an event
:icons: font
:relative_path: ./snaplock/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/./media/

Beginning with ONTAP 9.3, you can define how long a file is retained after an event occurs by using the SnapLock *Event Based Retention (EBR)* feature.

What you'll need

- You must be a SnapLock administrator to perform this task.

[Create a SnapLock administrator account](#)

- You must have logged in on a secure connection (SSH, console, or ZAPI).

About this task

The *event retention policy* defines the retention period for the file after the event occurs. The policy can be applied to a single file or all the files in a directory.

- If a file is not a WORM file, it will be committed to the WORM state for the retention period defined in the policy.
- If a file is a WORM file or a WORM appendable file, its retention period will be extended by the retention period defined in the policy.

You can use a Compliance-mode or Enterprise-mode volume.

EBR policies cannot be applied to files under a Legal Hold.

For advanced usage, see [Compliant WORM Storage Using NetApp SnapLock](#).

Using EBR to extend the retention period of already existing WORM files

EBR is convenient when you want to extend the retention period of already existing WORM files. For example, it might be your firm's policy to retain employee W-4 records in unmodified form for three years after the employee changes a withholding election. Another company policy might require that W-4 records be retained for five years after the employee is terminated.

In this situation, you could create an EBR policy with a five-year retention period. After the employee is terminated (the "event"), you would apply the EBR policy to the employee's W-4 record, causing its retention period to be extended. That will usually be easier than extending the retention period manually, particularly when a large number of files is involved.

Steps

1. Create an EBR policy:

```
snapshot event-retention policy create -vserver SVM_name -name policy_name  
-retention-period retention_period
```

The following command creates the EBR policy `employee_exit` on `vs1` with a retention period of ten years:

```
cluster1::>snapshot event-retention policy create -vserver vs1 -name  
employee_exit -retention-period 10years
```

2. Apply an EBR policy:

```
snapshot event-retention apply -vserver SVM_name -name policy_name -volume  
volume_name -path path_name
```

The following command applies the EBR policy `employee_exit` on `vs1` to all the files in the directory `d1`:

```
cluster1::>snapshot event-retention apply -vserver vs1 -name  
employee_exit -volume voll -path /d1
```

= Create an audit log

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You must create a SnapLock-protected audit log before performing a privileged delete or SnapLock volume move. The audit log records the creation and deletion of SnapLock administrator accounts, modifications to the log volume, whether privileged delete is enabled, privileged delete operations, and SnapLock volume move operations.

What you'll need

You must be a cluster administrator to create a SnapLock aggregate.

About this task

You cannot delete an audit log until the log file retention period has elapsed. You cannot modify an audit log even after the retention period has elapsed. This is true for both SnapLock Compliance and Enterprise modes.

In ONTAP 9.4 and earlier, you cannot use a SnapLock Enterprise volume for audit logging. You must use a SnapLock Compliance volume. In ONTAP 9.5 and later, you can use either a SnapLock Enterprise volume or a SnapLock Compliance volume for audit logging. In all cases, the audit log volume must be mounted at the junction path `/snaplock_audit_log`. No other volume can use this junction path.

You can find the SnapLock audit logs in the `/snaplock_log` directory under the root of the audit log volume, in subdirectories named `privdel_log` (privileged delete operations) and `system_log` (everything else). Audit log file names contain the timestamp of the first logged operation, making it easy to search for records by the approximate time that operations were executed.

- You can use the `snaplock log file show` command to view the log files on the audit log volume.
- You can use the `snaplock log file archive` command to archive the current log file and create a new one, which is useful in cases where you need to record audit log information in a separate file.

For more information, see the man pages for the commands.

A data protection volume cannot be used as a SnapLock audit log volume.

Steps

1. Create a SnapLock aggregate.

[Create a SnapLock aggregate](#)

2. On the SVM that you want to configure for audit logging, create a SnapLock volume.

[Create a SnapLock volume](#)

3. Configure the SVM for audit logging:

```
snaplock log create -vserver SVM_name -volume snaplock_volume_name -max
-file-size size -retention-period default_retention_period
```

The minimum default retention period for audit log files is six months. If the retention period of an affected file is longer than the retention period of the audit log, the retention period of the log inherits the retention period of the file. So, if the retention period for a file deleted using privileged delete is 10 months, and the retention period of the audit log is 8 months, the retention period of the log is extended to 10 months. For more information about retention time and default retention period, see [Set the retention time](#).

+

The following command configures SVM1 for audit logging using the SnapLock volume logVol. The audit log has a maximum size of 20 GB and is retained for eight months.

+

```
SVM1::> snaplock log create -vserver SVM1 -volume logVol -max-file-size  
20GB -retention-period 8months
```

1. On the SVM that you configured for audit logging, mount the SnapLock volume at the junction path /snaplock_audit_log.

[Mount a SnapLock volume](#)

= Verify SnapLock settings

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You can use the `volume file fingerprint start` and `volume file fingerprint dump` commands to view key information about files and volumes, including the file type (regular, WORM, or WORM appendable), the volume expiration date, and so forth.

Steps

1. Generate a file fingerprint:

```
volume file fingerprint start -vserver SVM_name -file file_path
```

```
svm1::> volume file fingerprint start -vserver svml -file  
/vol/sle/vol/f1  
File fingerprint operation is queued. Run "volume file fingerprint  
show -session-id 16842791" to view the fingerprint session status.
```

The command generates a session ID that you can use as input to the `volume file fingerprint dump` command.

You can use the `volume file fingerprint show` command with the session ID to monitor the progress of the fingerprint operation. Make sure that the operation has completed before attempting to display the fingerprint.

1. Display the fingerprint for the file:

```
volume file fingerprint dump -session-id session_ID
```

```
svm1::> volume file fingerprint dump -session-id 33619976
Vserver:svm1
Session-ID:33619976
Volume:slc_vol
Path:/vol/slclvol/f1

= Manage WORM files

= Manage WORM files

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can manage WORM files in the following ways:

- Commit files to WORM
- Commit Snapshot copies to WORM on a vault destination
- Mirror WORM files for disaster recovery
- Retain WORM files during litigation
- Delete WORM files

= Commit files to WORM

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can commit files to WORM (write once, read many) either manually or by committing them automatically. You can also create WORM appendable files.

== Commit files to WORM manually

You commit a file to WORM manually by making the file read-only. You can use any suitable command or program over NFS or CIFS to change the read-write attribute of a file to read-only. You might choose to manually commit files if you want to ensure an application has finished writing to a file so that the file isn't committed prematurely or if there are scaling issues for the autocommit scanner because of a high number of volumes.

What you'll need

- The file you want to commit must reside on a SnapLock volume.
- The file must be writable.

About this task

The volume ComplianceClock time is written to the `ctime` field of the file when the command or program is executed. The ComplianceClock time determines when the retention time for the file has been reached.

Steps

1. Use a suitable command or program to change the read-write attribute of a file to read-only.

In a UNIX shell, use the following command to make a file named `document.txt` read-only:

```
chmod -w document.txt
```

In a Windows shell, use the following command to make a file named `document.txt` read-only:

```
attrib +r document.txt
```

== Commit files to WORM automatically

The SnapLock autocommit feature enables you to commit files to WORM automatically. The autocommit feature commits a file to WORM state on a SnapLock volume if the file did not change for the autocommit-period duration. The autocommit feature is disabled by default.

What you'll need

- The files you want to autocommit must reside on a SnapLock volume.
- The SnapLock volume must be online.
- The SnapLock volume must be a read-write volume.

The SnapLock autocommit feature scans through all of the files in the volume and commits a file if it meets the autocommit requirement. There might be a time interval between when the file is ready for autocommit and when it is actually committed by the SnapLock autocommit scanner. However, the file is still protected from modifications and deletion by the file system as soon as it is eligible for autocommit.

About this task

The *autocommit period* specifies the amount of time that files must remain unchanged before they are autocommitted. Changing a file before the autocommit period has elapsed restarts the autocommit period for the file.

The following table shows the possible values for the autocommit period:

Value	Unit	Notes
none	-	The default.
5 - 5256000	minutes	-
1 - 87600	hours	-
1 - 3650	days	-
1 - 120	months	-
1 - 10	years	-

The minimum value is 5 minutes and the maximum value is 10 years.

Steps

1. Autocommit files on a SnapLock volume to WORM:

```
volume snaplock modify -vserver SVM_name -volume volume_name -autocommit  
-period autocommit_period
```

For a complete list of options, see the man page for the command.

The following command autocommits the files on volume `voll` of SVM `vs1`, as long as the files remain unchanged for 5 hours:

```
cluster1::>volume snaplock modify -vserver vs1 -volume voll  
-autocommit-period 5hours
```

== Create a WORM appendable file

A WORM appendable file retains data written incrementally, like log entries. You can use any suitable command or program to create a WORM appendable file, or you can use the SnapLock *volume append mode* feature to create WORM appendable files by default.

== Use a command or program to create a WORM appendable file

You can use any suitable command or program over NFS or CIFS to create a WORM appendable file. A WORM appendable file retains data written incrementally, like log entries. Data is appended to the file in 256 KB chunks. As each chunk is written, the previous chunk becomes WORM-protected. You cannot delete the file until the retention period has elapsed.

What you'll need

The WORM appendable file must reside on a SnapLock volume.

About this task

Data does not have to be written sequentially to the active 256 KB chunk. When data is written to byte $n \times 256\text{KB} + 1$ of the file, the previous 256 KB segment becomes WORM-protected.

Steps

1. Use a suitable command or program to create a zero-length file with the desired retention time.

In a UNIX shell, use the following command to set a retention time of 21 November 2020 6:00 a.m. on a zero-length file named `document.txt`:

```
touch -a -t 202011210600 document.txt
```

2. Use a suitable command or program to change the read-write attribute of the file to read-only.

In a UNIX shell, use the following command to make a file named `document.txt` read-only:

```
chmod 444 document.txt
```

3. Use a suitable command or program to change the read-write attribute of the file back to writable.

This step is not deemed a compliance risk because there is no data in the file.

+

In a UNIX shell, use the following command to make a file named `document.txt` writable:

+

```
chmod 777 document.txt
```

1. Use a suitable command or program to start writing data to the file.

In a UNIX shell, use the following command to write data to `document.txt`:

```
echo test data >> document.txt
```

Change the file permissions back to read-only when you no longer need to append data to the file.

== Use volume append mode to create WORM appendable files

Beginning with ONTAP 9.3, you can use the SnapLock *volume append mode* (VAM) feature to create WORM appendable files by default. A WORM appendable file retains data written incrementally, like log entries. Data is appended to the file in 256 KB chunks. As each chunk is written, the previous chunk becomes WORM-protected. You cannot delete the file until the retention period has elapsed.

What you'll need

- The WORM appendable file must reside on a SnapLock volume.
- The SnapLock volume must be unmounted and empty of Snapshot copies and user-created files.

About this task

Data does not have to be written sequentially to the active 256 KB chunk. When data is written to byte $n \times 256\text{KB} + 1$ of the file, the previous 256 KB segment becomes WORM-protected.

If you specify an autocommit period for the volume, WORM appendable files that are not modified for a period greater than the autocommit period are committed to WORM.

VAM is not supported on SnapLock audit log volumes.

Steps

1. Enable VAM:

```
volume snaplock modify -vserver SVM_name -volume volume_name -is-volume  
-append-mode-enabled true|false
```

For a complete list of options, see the man page for the command.

The following command enables VAM on volume vol1 of SVMvs1:

```
cluster1::>volume snaplock modify -vserver vs1 -volume vol1 -is  
-volume-append-mode-enabled true
```

2. Use a suitable command or program to create files with write permissions.

The files are WORM-appendable by default.

= Commit Snapshot copies to WORM on a vault destination
:icons: font
:relative_path: ./snaplock/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use SnapLock for SnapVault to WORM-protect Snapshot copies on secondary storage. You perform all of the basic SnapLock tasks on the SnapVault destination. The destination volume is automatically mounted read-only, so there is no need to explicitly commit the Snapshot copies to WORM; therefore, creating scheduled Snapshot copies on the destination volume using SnapMirror policies is not supported.

Before you begin

- The source cluster must be running ONTAP 8.2.2 or later.
- The source and destination aggregates must be 64-bit.
- The source volume cannot be a SnapLock volume.
- The source and destination volumes must be created in peered clusters with peered SVMs.

For more information, see [Cluster Peering](#).

- If volume autogrow is disabled, the free space on the destination volume must be at least five percent more than the used space on the source volume.

About this task

The source volume can use NetApp or non-NetApp storage. For non-NetApp storage, you must use FlexArray Virtualization.

You cannot rename a Snapshot copy that is committed to the WORM state.

You can clone SnapLock volumes, but you cannot clone files on a SnapLock volume.

LUNs are not supported on SnapLock volumes. Although it is possible to move LUNs onto a SnapLock volume using legacy technology, this is not a supported operation, nor is any other operation involving LUNs on a SnapLock volume. Beginning with ONTAP 9.9.0, LUNs on a SnapLock volume are supported in SnapLock *only* for SnapVault relationships where a Snapshot copy of a non-SnapLock source volume is replicated and locked on a SnapLock destination. These Snapshot copies can contain LUNs.

Beginning with ONTAP 9.13.1, you can instantaneously restore a locked Snapshot copy on the destination SnapLock volume of a SnapLock for SnapVault relationship by creating a FlexClone with the `snaplock-type` option set to “non-snaplock” and specifying the Snapshot copy as the “parent-snapshot” when executing the volume clone creation operation. Learn more about [creating a FlexClone volume with a SnapLock type](#).

For MetroCluster configurations, you should be aware of the following:

- You can create a SnapVault relationship only between sync-source SVMs, not between a sync-source SVM and a sync-destination SVM.
- You can create a SnapVault relationship from a volume on a sync-source SVM to a data-serving SVM.
- You can create a SnapVault relationship from a volume on a data-serving SVM to a DP volume on a sync-source SVM.

The following illustration shows the procedure for initializing a SnapVault relationship:

Steps

1. Identify the destination cluster.
2. On the destination cluster, install the SnapLock license, initialize the ComplianceClock, and, if you are using an ONTAP release earlier than 9.10.1, create a SnapLock aggregate, as described in [SnapLock workflow](#).
3. On the destination cluster, create a SnapLock destination volume of type DP that is either the same or greater in size than the source volume:

```
volume create -vserver SVM_name -volume volume_name -aggregate  
aggregate_name -snaplock-type compliance|enterprise -type DP -size size
```

Beginning with ONTAP 9.10.1, SnapLock and non-SnapLock volumes can exist on the same aggregate; therefore, you are no longer required to create a separate SnapLock aggregate if you are using ONTAP 9.10.1. You use the volume `-snaplock-type` option to specify a Compliance or Enterprise SnapLock volume type. In ONTAP releases earlier than ONTAP 9.10.1, the SnapLock mode, Compliance or Enterprise, is inherited from the aggregate. Version-flexible destination volumes are not supported. The language setting of the destination volume must match the language setting of the source volume.

+

The following command creates a 2 GB SnapLock Compliance volume named `dstvolB` in `SVM2` on the aggregate `node01_aggr`:

+

```
cluster2::> volume create -vserver SVM2 -volume dstvolB -aggregate  
node01_aggr -snaplock-type compliance -type DP -size 2GB
```

1. On the destination cluster, set the default retention period, as described in [Set the default retention period](#).

A SnapLock volume that is a vault destination has a default retention period assigned to it. The value for this period is initially set to a minimum of 0 years for SnapLock Enterprise volumes and a maximum of 30 years for SnapLock Compliance volumes. Each NetApp Snapshot copy is committed with this default retention period at first. The retention period can be extended later, if needed. For more information, see [Set retention time overview](#).

1. [Create a new replication relationship](#) between the non-SnapLock source and the new SnapLock destination you created in Step 3.

This example creates a new SnapMirror relationship with destination SnapLock volume `dstvolB` using a policy of `XDPDefault` to vault Snapshot copies labeled daily and weekly on an hourly schedule:

```
cluster2::> snapmirror create -source-path SVM1:srcvolA -destination  
-path SVM2:dstvolB -vserver SVM2 -policy XDPDefault -schedule hourly
```

[Create a custom replication policy](#) or a [custom schedule](#) if the available defaults are not suitable.

1. On the destination SVM, initialize the SnapVault relationship created in Step 5:

```
snapmirror initialize -destination-path destination_path
```

The following command initializes the relationship between the source volume `srcvolA` on SVM1 and the destination volume `dstvolB` on SVM2:

```
cluster2::> snapmirror initialize -destination-path SVM2:dstvolB
```

2. After the relationship is initialized and idle, use the `snapshot show` command on the destination to verify the SnapLock expiry time applied to the replicated Snapshot copies.

This example lists the Snapshot copies on volume `dstvolB` that have the SnapMirror label and the SnapLock expiration date:

```
cluster2::> snapshot show -vserver SVM2 -volume dstvolB -fields  
snapmirror-label, snaplock-expiry-time
```

[Volume backup using SnapVault](#)

= Mirror WORM files for disaster recovery

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can use SnapMirror to replicate WORM files to another geographic location for disaster recovery and other purposes. Both the source volume and destination volume must be configured for SnapLock, and both volumes must have the same SnapLock mode, Compliance or Enterprise. All key SnapLock properties of the volume and files are replicated.

Prerequisites

The source and destination volumes must be created in peered clusters with peered SVMs. For more information, see [Cluster and SVM peering](#).

About this task

- Beginning with ONTAP 9.5, you can replicate WORM files with the XDP (extended data protection) type SnapMirror relationship rather than the DP (data protection) type relationship. XDP mode is ONTAP version-independent, and is able to differentiate files stored in the same block, making it much easier to resync replicated Compliance-mode volumes. For information on how to convert an existing DP-type relationship to an XDP-type relationship, see [Data Protection](#).
- A resync operation on a DP type SnapMirror relationship fails for a Compliance-mode volume if SnapLock determines that it will result in a loss of data. If a resync operation fails, you can use the `volume clone create` command to make a clone of the destination volume. You can then resync

the source volume with the clone.

- A SnapMirror relationship of type XDP between SnapLock compliant volumes supports a resync after a break even if data on the destination has diverged from the source post the break.

On a resync, when data divergence is detected between the source and the destination beyond the common snapshot, a new snapshot is cut on the destination to capture this divergence. The new snapshot and the common snapshot are both locked with a retention time as follows:

- The volume expiry time of the destination
- If the volume expiry time is in the past or has not been set, then the snapshot is locked for a period of 30 days
- If the destination has legal-holds, the actual volume expiry period is masked and shows up as ‘indefinite’, however the snapshot is locked for the duration of the actual volume expiry period.

If the destination volume has an expiry period that is later than the source, the destination expiry period is retained and will not be overwritten by the expiry period of the source volume post the resync.

If the destination has legal-holds placed on it that differ from the source, a resync is not allowed. The source and destination must have identical legal-holds or all legal-holds on the destination must be released before a resync is attempted.

A locked Snapshot copy on the destination volume created to capture the divergent data can be copied to the source using the CLI by running the `snapmirror update -s snapshot` command. The snapshot once copied will continue to be locked at the source as well.

- SVM data protection relationships are not supported.
- Load-sharing data protection relationships are not supported.

The following illustration shows the procedure for initializing a SnapMirror relationship:

Beginning with ONTAP 9.12.1, you can use System Manager to set up SnapMirror replication of WORM files.

Steps

1. Navigate to **Storage > Volumes**.
2. Click **Show/Hide** and select **SnapLock Type** to display the column in the **Volumes** window.
3. Locate a SnapLock volume.
4. Click  and select **Protect**.
5. Choose the destination cluster and the destination storage VM.
6. Click **More Options**.
7. Select **Show legacy policies** and select **DPDefault (legacy)**.
8. In the **Destination Configuration details** section, select **Override transfer schedule** and select **hourly**.
9. Click **Save**.
10. To the left of the source volume name, click the arrow to expand the volume details, and on the right side of the page, review the remote SnapMirror protection details.
11. On the remote cluster, navigate to **Protection Relationships**.
12. Locate the relationship and click the destination volume name to view the relationship details.

13. Verify that the destination volume SnapLock type and other SnapLock information.
1. Identify the destination cluster.
2. On the destination cluster, install the SnapLock license, initialize the ComplianceClock, and, if you are using an ONTAP release earlier than 9.10.1, create a SnapLock aggregate.
3. On the destination cluster, create a SnapLock destination volume of type DP that is either the same size as or greater in size than the source volume:

```
volume create -vserver SVM_name -volume volume_name -aggregate aggregate_name  
-snaplock-type compliance|enterprise -type DP -size size
```

 Beginning with ONTAP 9.10.1, SnapLock and non-SnapLock volumes can exist on the same aggregate; therefore, you are no longer required to create a separate SnapLock aggregate if you are using ONTAP 9.10.1. You use the volume -snaplock-type option to specify a Compliance or Enterprise SnapLock volume type. In ONTAP releases earlier than ONTAP 9.10.1, the SnapLock mode—Compliance or Enterprise—is inherited from the aggregate. Version-flexible destination volumes are not supported. The language setting of the destination volume must match the language setting of the source volume.

The following command creates a 2 GB SnapLock Compliance volume named dstvolB in SVM2 on the aggregate node01_aggr:

```
cluster2::> volume create -vserver SVM2 -volume dstvolB -aggregate  
node01_aggr -snaplock-type compliance -type DP -size 2GB
```

4. On the destination SVM, create a SnapMirror policy:

```
snapmirror policy create -vserver SVM_name -policy policy_name
```

The following command creates the SVM-wide policy SVM1-mirror:

```
SVM2::> snapmirror policy create -vserver SVM2 -policy SVM1-mirror
```

5. On the destination SVM, create a SnapMirror schedule:

```
job schedule cron create -name schedule_name -dayofweek day_of_week -hour hour  
-minute minute
```

The following command creates a SnapMirror schedule named weekendcron:

```
SVM2::> job schedule cron create -name weekendcron -dayofweek "Saturday,  
Sunday" -hour 3 -minute 0
```

6. On the destination SVM, create a SnapMirror relationship:

```
snapmirror create -source-path source_path -destination-path destination_path  
-type XDP|DP -policy policy_name -schedule schedule_name
```

The following command creates a SnapMirror relationship between the source volume `srcvolA` on SVM1 and the destination volume `dstvolB` on SVM2, and assigns the policy `SVM1-mirror` and the schedule `weekendcron`:

```
SVM2::> snapmirror create -source-path SVM1:srcvolA -destination-path  
SVM2:dstvolB -type XDP -policy SVM1-mirror -schedule weekendcron
```

The XDP type is available in ONTAP 9.5 and later. You must use the DP type in ONTAP 9.4 and earlier.

7. On the destination SVM, initialize the SnapMirror relationship:

```
snapmirror initialize -destination-path destination_path
```

The initialization process performs a *baseline transfer* to the destination volume. SnapMirror makes a Snapshot copy of the source volume, then transfers the copy and all the data blocks that it references to the destination volume. It also transfers any other Snapshot copies on the source volume to the destination volume.

The following command initializes the relationship between the source volume `srcvolA` on SVM1 and the destination volume `dstvolB` on SVM2:

```
SVM2::> snapmirror initialize -destination-path SVM2:dstvolB
```

[Volume disaster recovery preparation](#)

[Data protection](#)

= Retain WORM files during litigation using Legal Hold

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

Beginning with ONTAP 9.3, you can retain Compliance-mode WORM files for the duration of a litigation by using the *Legal Hold* feature.

What you'll need

- You must be a SnapLock administrator to perform this task.

[Create a SnapLock administrator account](#)

- You must have logged in on a secure connection (SSH, console, or ZAPI).

About this task

A file under a Legal Hold behaves like a WORM file with an indefinite retention period. It is your responsibility to specify when the Legal Hold period ends.

The number of files you can place under a Legal Hold depends on the space available on the volume.

Steps

1. Start a Legal Hold:

```
snaplock legal-hold begin -litigation-name litigation_name -volume  
volume_name -path path_name
```

The following command starts a Legal Hold for all the files in vol1:

```
cluster1::>snaplock legal-hold begin -litigation-name litigation1  
-volume vol1 -path /
```

2. End a Legal Hold:

```
snaplock legal-hold end -litigation-name litigation_name -volume  
volume_name -path path_name
```

The following command ends a Legal Hold for all the files in vol1:

```
cluster1::>snaplock legal-hold end -litigation-name litigation1  
-volume vol1 -path /
```

= Delete WORM files overview
:icons: font
:relative_path: ./snaplock/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

You can delete Enterprise-mode WORM files during the retention period using the privileged delete feature.

Before you can use this feature, you must create a SnapLock administrator account and then using the account, enable the feature.

== Create a SnapLock administrator account

You must have SnapLock administrator privileges to perform a privileged delete. These privileges are defined in the vsadmin-snaplock role. If you have not already been assigned that role, you can ask your cluster administrator to create an SVM administrator account with the SnapLock administrator role.

What you'll need

- You must be a cluster administrator to perform this task.
- You must have logged in on a secure connection (SSH, console, or ZAPI).

Steps

1. Create an SVM administrator account with the SnapLock administrator role:

```
security login create -vserver SVM_name -user-or-group-name
user_or_group_name -application application -authmethod
authentication_method -role role -comment comment
```

The following command enables the SVM administrator account SnapLockAdmin with the predefined vsadmin-snaplock role to access SVM1 using a password:

```
cluster1::> security login create -vserver SVM1 -user-or-group-name
SnapLockAdmin -application ssh -authmethod password -role vsadmin-
snaplock
```

== Enable the privileged delete feature

You must explicitly enable the privileged delete feature on the Enterprise volume that contains the WORM files you want to delete.

About this task

The value of the -privileged-delete option determines whether privileged delete is enabled. Possible values are enabled, disabled, and permanently-disabled.

permanently-disabled is the terminal state. You cannot enable privileged delete on the volume after you set the state to permanently-disabled.

Steps

1. Enable privileged delete for a SnapLock Enterprise volume:

```
volume snaplock modify -vserver SVM_name -volume volume_name -privileged-delete disabled|enabled|permanently-disabled
```

The following command enables the privileged delete feature for the Enterprise volume dataVol on SVM1:

```
SVM1::> volume snaplock modify -vserver SVM1 -volume dataVol -privileged-delete enabled
```

== Delete Enterprise-mode WORM files

You can use the privileged delete feature to delete Enterprise-mode WORM files during the retention period.

What you'll need

- You must be a SnapLock administrator to perform this task.
- You must have created a SnapLock audit log and enabled the privileged delete feature on the Enterprise volume.

About this task

You cannot use a privileged delete operation to delete an expired WORM file. You can use the `volume file retention show` command to view the retention time of the WORM file that you want to delete. For more information, see the man page for the command.

Step

1. Delete a WORM file on an Enterprise volume:

```
volume file privileged-delete -vserver SVM_name -file file_path
```

The following command deletes the file /vol/dataVol/f1 on the SVM SVM1:

```
SVM1::> volume file privileged-delete -file /vol/dataVol/f1
```

= Move a SnapLock volume

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

Beginning with ONTAP 9.8, you can move a SnapLock volume to a destination aggregate of the same type, either Enterprise to Enterprise, or Compliance to Compliance. You must be assigned the SnapLock security role to move a SnapLock volume.

== Create a SnapLock security administrator account

You must have SnapLock security administrator privileges to perform a SnapLock volume move. This privilege is granted to you with the *snaplock* role, introduced in ONTAP 9.8. If you have not already been assigned that role, you can ask your cluster administrator to create a SnapLock security user with this SnapLock security role.

What you'll need

- You must be a cluster administrator to perform this task.
- You must have logged in on a secure connection (SSH, console, or ZAPI).

About this task

The *snaplock* role is associated with the admin SVM, unlike the *vsadmin-snaplock* role, which is associated with the data SVM.

Step

1. Create an SVM administrator account with the SnapLock administrator role:

```
security login create -vserver SVM_name -user-or-group-name  
user_or_group_name -application application -authmethod  
authentication_method -role role -comment comment
```

The following command enables the SVM administrator account *SnapLockAdmin* with the predefined *snaplock* role to access admin SVM *cluster1* using a password:

```
cluster1::> security login create -vserver cluster1 -user-or-group  
-name SnapLockAdmin -application ssh -authmethod password -role  
snaplock
```

== Move a SnapLock volume

You can use the `volume move` command to move a SnapLock volume to a destination aggregate.

What you'll need

- You must have created a SnapLock-protected audit log before performing SnapLock volume move.

[Create an audit log.](#)

- If you are using a version of ONTAP earlier than ONTAP 9.10.1, the destination aggregate must be the same SnapLock type as the SnapLock volume you want to move; either Compliance to Compliance or Enterprise to Enterprise. Beginning with ONTAP 9.10.1, this restriction is removed and an aggregate can include both Compliance and Enterprise SnapLock volumes, as well as non-SnapLock volumes.
- You must be a user with the SnapLock security role.

Steps

1. Using a secure connection, log in to the ONTAP cluster management LIF:

```
ssh snaplock_user@cluster_mgmt_ip
```

2. Move a SnapLock volume:

```
volume move start -vserver SVM_name -volume SnapLock_volume_name  
-destination-aggregate destination_aggregate_name
```

3. Check the status of the volume move operation:

```
volume move show -volume SnapLock_volume_name -vserver SVM_name -fields  
volume,phase,vserver
```

= Lock a Snapshot copy for protection against ransomware attacks

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

Beginning with ONTAP 9.12.1, you can lock a Snapshot copy on a non-SnapLock volume to provide protection from ransomware attacks. Locking Snapshot copies ensures that they can't be deleted accidentally or maliciously.

You use the SnapLock compliance clock feature to lock Snapshot copies for a specified period so that they cannot be deleted until the expiration time is reached. Locking Snapshot copies makes them tamperproof, protecting them from ransomware threats. You can use locked Snapshot copies to recover data if a volume is compromised by a ransomware attack.

Tamperproof Snapshot copy requirements and considerations

- If you are using the ONTAP CLI, all nodes in the cluster must be running ONTAP 9.12.1 or later. If you are using System Manager, all nodes must be running ONTAP 9.13.1 or later.
- The SnapLock license must be installed on the cluster.

For details, see [Installing the SnapLock license](#).

- The compliance clock on the cluster must be initialized.

For details, see [Initialize the Compliance Clock](#).

- When Snapshot locking is enabled on a volume, you can upgrade the clusters to a version of ONTAP later than ONTAP 9.12.1; however, you cannot revert to an earlier version of ONTAP until all locked Snapshot copies have reached their expiration date and are deleted and Snapshot copy locking is disabled.
- When a Snapshot is locked, the volume expiry time is set to the expiry time of the Snapshot copy. If more than one Snapshot copy is locked, the volume expiry time reflects the largest expiry time among all Snapshot copies.
- The retention period for locked Snapshot copies takes precedence over the Snapshot copy keep count, which means the keep count limit is not honored if the Snapshot copy retention period for locked Snapshot copies has not expired.
- In a SnapMirror relationship, you can set a retention period on a mirror-vault policy rule, and the retention period is applied for Snapshot copies replicated to the destination if the destination volume has Snapshot copy locking enabled. The retention period takes precedence over keep count; for example, Snapshot copies that have not passed their expiry will be retained even if the keep count is exceeded.
- You can rename a Snapshot copy on a non-SnapLock volume. Snapshot rename operations on the

primary volume of a SnapMirror relationship are reflected on the secondary volume only if the policy is MirrorAllSnapshots. For other policy types, the renamed Snapshot copy is not propagated during updates.

- If you are using the ONTAP CLI, you can restore a locked Snapshot copy with the `volume snapshot restore` command only if the locked Snapshot copy is the most recent. If there are any unexpired Snapshot copies later than the one being restored, the Snapshot copy restore operation fails.

Features supported with tamperproof Snapshot copies

- FlexGroup volumes

Snapshot copy locking is supported on FlexGroup volumes. Snapshot locking occurs only on the root constituent Snapshot copy. Deleting the FlexGroup volume is allowed only if the root constituent expiration time has passed.

- FlexVol to FlexGroup conversion

You can convert a FlexVol volume with locked Snapshot copies to a FlexGroup volume. Snapshot copies remain locked after the conversion.

- Volume clone and file clone

You can create volume clones and file clones from a locked Snapshot copy.

Unsupported features

The following features currently are not supported with tamperproof Snapshot copies:

- Consistency groups
- FabricPool
- FlexCache volumes
- SMtape
- SnapCenter
- SnapMirror Business Continuity (SM-BC)
- SnapMirror Synchronous
- SVM data mobility

== Enable Snapshot copy locking when creating a volume

Beginning with ONTAP 9.12.1, you can enable Snapshot copy locking when you create a new volume or when you modify an existing volume by using the `-snapshot-locking-enabled` option with the `volume create` and `volume modify` commands in the CLI. Beginning with ONTAP 9.13.1, you can use System Manager to enable Snapshot copy locking.

1. Navigate to **Storage > Volumes** and select **Add**.
2. In the **Add Volume** window, choose **More Options**.
3. Enter the volume name, size, export policy and share name.
4. Select **Enable Snapshot locking**. This selection is not displayed if the SnapLock license is not installed.

5. If it is not already enabled, select **Initialize SnapLock Compliance Clock**.
6. Save your changes.
7. In the **Volumes** window, select the volume you updated and choose **Overview**.
8. Verify that **SnapLock Snapshot Copy Locking** displays as **Enabled**.

1. To create a new volume and enable Snapshot copy locking, enter the following command:

```
volume create -vserver vserver_name -volume volume_name -snapshot-locking
-enabled true
```

The following command enables Snapshot copy locking on a new volume named vol1:

```
> volume create -volume vol1 -aggregate aggr1 -size 100m -snapshot
-locking-enabled true
Warning: Snapshot copy locking is being enabled on volume "vol1" in
Vserver "vs1". It cannot be disabled until all locked Snapshot copies
are past their expiry time. A volume with unexpired locked Snapshot
copies cannot be deleted.
Do you want to continue: {yes|no}: y
[Job 32] Job succeeded: Successful
```

== Enable Snapshot copy locking on an existing volume

Beginning with ONTAP 9.12.1, you can enable Snapshot copy locking on an existing volume using the ONTAP CLI. Beginning with ONTAP 9.13.1, you can use System Manager to enable Snapshot copy locking on an existing volume.

1. Navigate to **Storage > Volumes**.
2. Select  and choose **Edit > Volume**.
3. In the **Edit Volume** window, locate the Snapshot Copies (Local) Settings section and select **Enable Snapshot locking**.

This selection is not displayed if the SnapLock license is not installed.

4. If it is not already enabled, select **Initialize SnapLock Compliance Clock**.
5. Save your changes.
6. In the **Volumes** window, select the volume you updated and choose **Overview**.
7. Verify that **SnapLock Snapshot Copy Locking** displays as **Enabled**.

1. To modify an existing volume to enable Snapshot copy locking, enter the following command:

```
volume modify -vserver vserver_name -volume volume_name -snapshot-locking
-enabled true
```

== Create a locked Snapshot copy policy and apply retention

Beginning with ONTAP 9.12.1, you can create Snapshot copy policies to apply a Snapshot copy retention period and apply the policy to a volume to lock Snapshot copies for the specified period. You can also lock a Snapshot copy by manually setting a retention period. Beginning with ONTAP 9.13.1, you can use System Manager to create Snapshot copy locking policies and apply them to a volume.

==== Create a Snapshot copy locking policy

1. Navigate to **Storage > Storage VMs** and select a storage VM.
2. Select **Settings**.
3. Locate **Snapshot Policies** and select .
4. In the **Add Snapshot Policy** window, enter the policy name.
5. Select .
6. Provide the Snapshot copy schedule details, including the schedule name, maximum Snapshot copies to keep, and SnapLock retention period.
7. In the **SnapLock Retention Period** column, enter the number of hours, days, months or years to retain the Snapshot copies. For example, a Snapshot copy policy with a retention period of 5 days locks a Snapshot copy for 5 days from the time it is created, and it cannot be deleted during that time. The following retention period ranges are supported:
 - Years: 0 - 100
 - Months: 0 - 1200
 - Days: 0 - 36500
 - Hours: 0 - 24
8. Save your changes.

1. To create a Snapshot copy policy, enter the following command:

```
volume snapshot policy create -policy policy_name -enabled true -schedule1
schedule1_name -count1 maximum_snapshot_copies -retention-period1
_retenion_period
```

The following command creates a Snapshot copy locking policy:

```
cluster1> volume snapshot policy create -policy policy_name -enabled
true -schedule1 5min -count1 5 -retention-period1 "1 months"
```

==== Apply a locking policy to a volume

1. Navigate to **Storage > Volumes**.
2. Select  and choose **Edit > Volume**.
3. In the **Edit Volume** window, select **Schedule Snapshot copies**.

4. Select the locking Snapshot copy policy from the list.
 5. If Snapshot copy locking is not already enabled, select **Enable Snapshot locking**.
 6. Save your changes.
1. To apply a Snapshot copy locking policy to an existing volume, enter the following command:
- ```
volume modify -volume volume_name -vserver vserver_name -snapshot-policy policy_name
```
- ==== Apply retention period during manual Snapshot copy creation**

You can apply a Snapshot copy retention period when you manually create a Snapshot copy. Snapshot copy locking must be enabled on the volume, otherwise, the retention period setting is ignored.
1. Navigate to **Storage > Volumes** and select a volume.
  2. In the volume details page, select the **Snapshot copies** tab.
  3. Select  **Add**.
  4. Enter the Snapshot copy name and the SnapLock expiration time. You can select the calendar to choose the retention expiration date and time.
  5. Save your changes.
  6. In the **Volumes > Snapshot Copies** page, select **Show/Hide** and choose **SnapLock Expiration Time** to display the **SnapLock Expiration Time** column and verify that the retention time is set.
1. To create a Snapshot copy manually and apply a locking retention period, enter the following command:
- ```
volume snapshot create -volume volume_name -snapshot snapshot_copy_name -snaplock-expiry-time expiration_date_time
```
- The following command creates a new Snapshot copy and sets the retention period:
- ```
cluster1> volume snapshot create -vserver vs1 -volume vol1 -snapshot snap1 -snaplock-expiry-time "11/10/2022 09:00:00"
```
- ==== Apply retention period to an existing Snapshot copy**
1. Navigate to **Storage > Volumes** and select a volume.
  2. In the volume details page, select the **Snapshot copies** tab.
  3. Select the Snapshot copy, select , and choose **Modify SnapLock Expiration Time**. You can select the calendar to choose the retention expiration date and time.
  4. Save your changes.
  5. In the **Volumes > Snapshot Copies** page, select **Show/Hide** and choose **SnapLock Expiration Time** to display the **SnapLock Expiration Time** column and verify that the retention time is set.

1. To manually apply a retention period to an existing Snapshot copy, enter the following command:

```
volume snapshot modify-snaplock-expiry-time -volume volume_name -snapshot snapshot_copy_name -expiry-time expiration_date_time
```

The following example applies a retention period to an existing Snapshot copy:

```
cluster1> volume snapshot modify-snaplock-expiry-time -volume vol1
-snapshot snap2 -expiry-time "11/10/2022 09:00:00"
```

```
= SnapLock APIs
:icons: font
:relative_path: ./snaplock/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/./media/
```

You can use Zephyr APIs to integrate with SnapLock functionality in scripts or workflow automation. The APIs use XML messaging over HTTP, HTTPS, and Windows DCE/RPC. For more information, see [ONTAP Automation documentation](#).

**== file-fingerprint-abort**

Abort a file fingerprint operation.

**== file-fingerprint-dump**

Display file fingerprint information.

**== file-fingerprint-get-iter**

Display the status of file fingerprint operations.

**== file-fingerprint-start**

Generate a file fingerprint.

**== snaplock-archive-vserver-log**

Archive the active audit log file.

**== snaplock-create-vserver-log**

Create an audit log configuration for an SVM.

**== snaplock-delete-vserver-log**

Delete an audit log configuration for an SVM.

**== snaplock-file-privileged-delete**

Execute a privileged delete operation.

**== snaplock-get-file-retention**

Get the retention period of a file.

**== snaplock-get-node-compliance-clock**

Get the node ComplianceClock date and time.

**== snaplock-get-vserver-active-log-files-iter**

Display the status of active log files.

**== snaplock-get-vserver-log-iter**

Display the audit log configuration.

== snaplock-modify-vserver-log

Modify the audit log configuration for an SVM.

== snaplock-set-file-retention

Set the retention time for a file.

== snaplock-set-node-compliance-clock

Set the node ComplianceClock date and time.

== snaplock-volume-set-privileged-delete

Set the privileged-delete option on a SnapLock Enterprise volume.

== volume-get-snaplock-attrs

Get the attributes of a SnapLock volume.

== volume-set-snaplock-attrs

Set the attributes of a SnapLock volume.

= Consistency groups management

= Consistency groups overview

:icons: font

:relative\_path: ./consistency-groups/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

A consistency group is a collection of volumes that are managed as a single unit. In ONTAP, consistency groups provide easy management and a protection guarantee for an application workload spanning multiple volumes.

You can use consistency groups to simplify your storage management. Imagine you have an important database spanning twenty LUNs. You could manage the LUNs on an individual basis or treat the LUNs as a solitary dataset, organizing them into a single consistency group.

Consistency groups facilitate application workload management, providing easily configured local and remote protection policies and simultaneous crash-consistent or application-consistent Snapshot copies of a collection of volumes at a point in time. Snapshots in consistency groups enable an entire application workload to be restored.

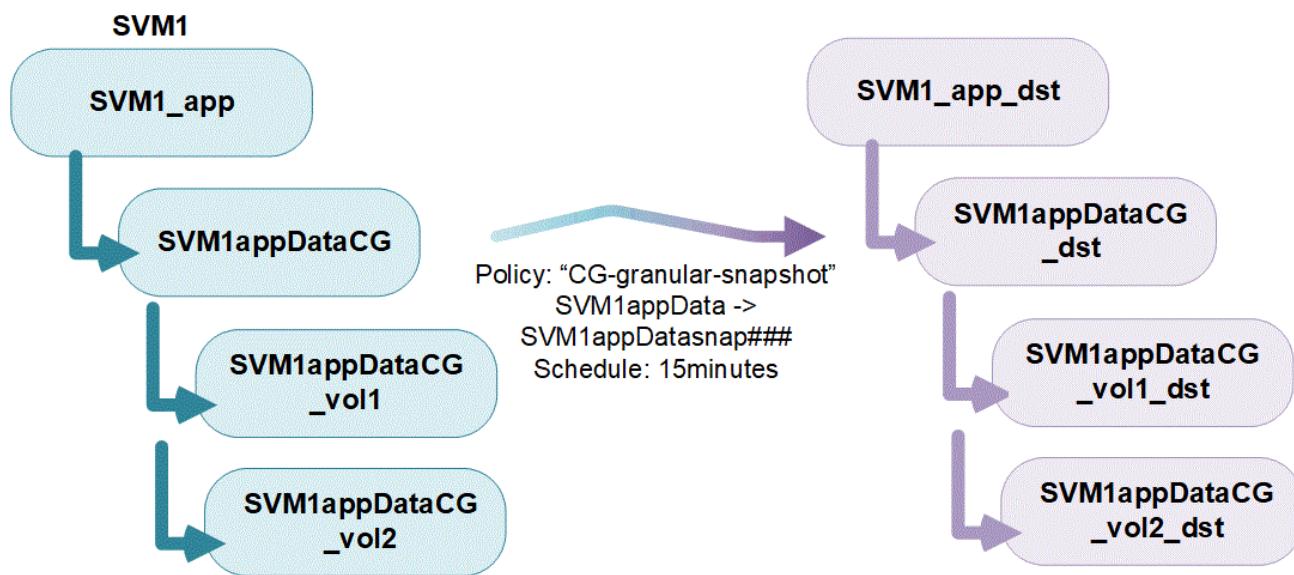

== Understand consistency groups

Consistency groups support any FlexVol volume regardless of protocol (NAS, SAN, or NVMe) and can be managed through the ONTAP REST API or in System Manager under the **Storage > Consistency Groups** menu item.

Consistency groups can exist as individual entities—as a collection of volumes—or in a hierarchical relationship, which consists of other consistency groups. Individual volumes can have their own volume-granular snapshot policy. In addition, there can be a consistency group-wide snapshot policy. The

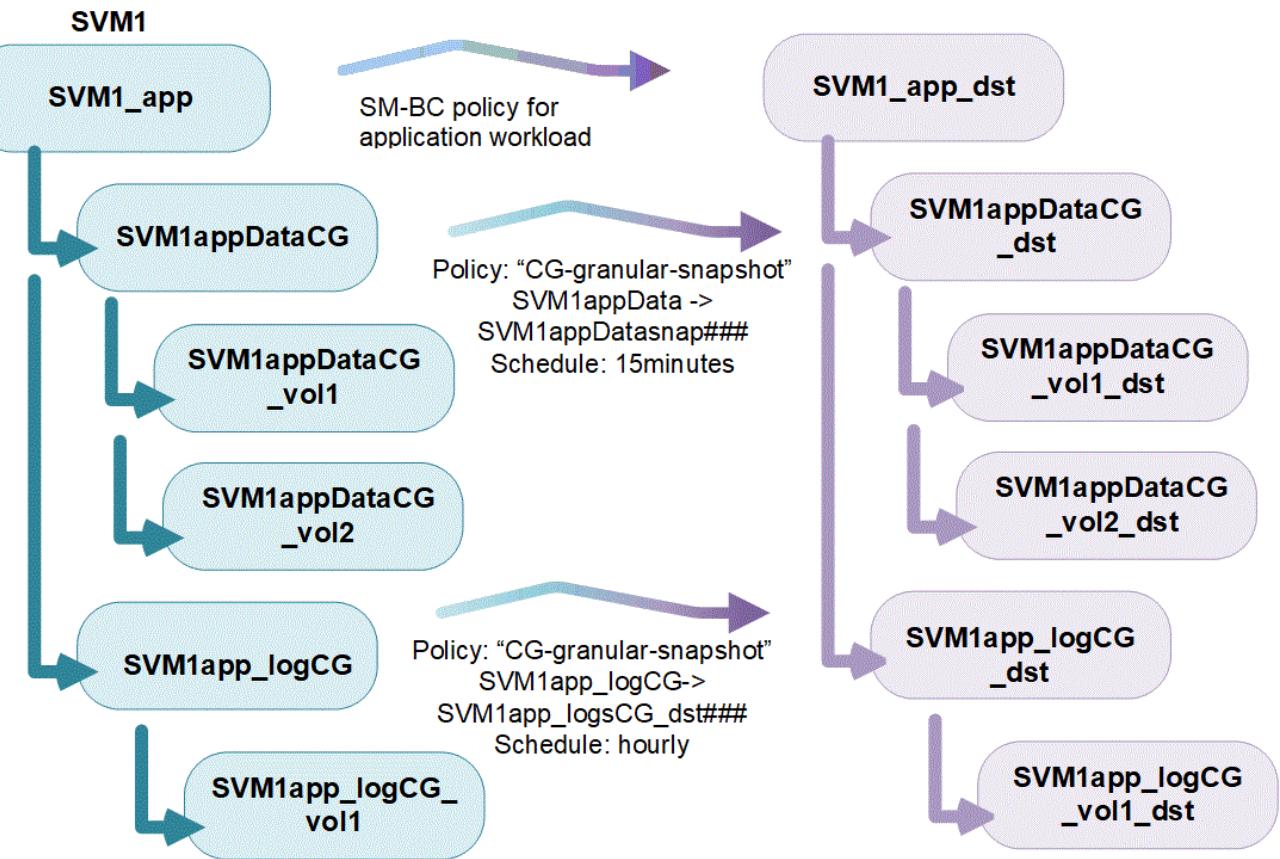

consistency group can only have one SnapMirror Business Continuity (SM-BC) relationship and shared SM-BC policy, which can be used to recover the entire consistency group.

The following diagram illustrates how you might use an individual consistency group. The data for an application hosted on SVM1 spans two volumes: vol1 and vol2. A Snapshot policy on the consistency group captures snapshots of the data every 15 minutes.

Larger application workloads might require multiple consistency groups. In these situations, you can create hierarchical consistency groups, where a single consistency group becomes the child components of a parent consistency group. The parent consistency group can include up to five child consistency groups. Like in individual consistency groups, a remote SM-BC protection policy can be applied to the entire configuration of consistency groups (parent and children) to recover the application workload.

In the following example, an application is hosted on SVM1. The administrator has created a parent consistency group, SVM1\_app, which includes two child consistency groups: SVM1appDataCG for the data and SVM1app\_logCG for the logs. Each child consistency group has its own snapshot policy. Snapshots of the volumes in SVM1appDataCG are taken every 15 minutes. Snapshots of SVM1app\_logCG are taken hourly. The parent consistency group SVM1\_app has an SM-BC policy which replicates the data to ensure continued service in the event of a disaster.

Beginning with ONTAP 9.12.1, consistency groups support [cloning](#) and modifying the members of the consistency by [adding or removing volumes](#) in both System Manager and the ONTAP REST API. Beginning in ONTAP 9.12.1, the ONTAP REST API also supports:

- Creating consistency groups with new NFS or SMB volumes or NVMe namespaces.
- Adding new or existing NFS or SMB volumes or NVMe namespaces to existing consistency groups.

For more information about the ONTAP REST API, refer to [ONTAP REST API reference documentation](#).

#### == Monitor consistency groups

Beginning in ONTAP 9.13.1, consistency groups offer real-time and historical capacity and performance monitoring, offering insights about the performance of applications and individual consistency groups.

Consistency group monitoring data is maintained for up to one year. You can track metrics for:

- Performance: IOPS, latency, and throughput
- Capacity: Size, available capacity, used capacity

You can retrieve historical metrics only with the REST API. Historical metrics are not viewable in System Manager.

#### == Protect consistency groups

Consistency groups offer protection through:

- Snapshot policies

- [SnapMirror Business Continuity \(SM-BC\)](#)
- [MetroCluster support](#) (beginning 9.11.1)
- [Asynchronous SnapMirror](#) (beginning 9.13.1)

Creating a consistency group does not automatically enable protection. Local and remote protection policies can be set when creating or after creating a consistency group.

To configure protection on a consistency group, see [Protect a consistency group](#).

In order to utilize remote protection, you must meet the requirements for [SnapMirror Business Continuity deployments](#).

SM-BC relationships cannot be established on volumes mounted for NAS access.

== Application and component tags

Beginning in ONTAP 9.12.1, consistency groups support component and application tagging. Application and component tags are a management tool, enabling you to filter and identify different workloads in your consistency groups.

There are two types of tags:

- **Application tags:** these apply to individual and parent consistency groups. Application tags provide labeling for workloads such as MongoDB, Oracle, or SQL Server. The default application tag for consistency groups is Other.
- **Component tags:** Children in hierachal consistency groups have component tags instead of application tags. The options for component tags are "data", "logs", or "other". The default value is Other.

You can apply tags when creating consistency groups or after the consistency groups have been created. If the consistency group has an SM-BC relationship, you must use **Other** as the application or component tag.

== Consistency groups in MetroCluster configurations

Beginning with ONTAP 9.11.1, you can provision consistency groups with new volumes on a cluster within a MetroCluster configuration. These volumes are provisioned on mirrored aggregates.

After they are provisioned, you can move volumes associated with consistency groups between mirrored and unmirrored aggregates. Therefore, volumes associated with consistency groups can be located on mirrored aggregates, unmirrored aggregates, or both. You can modify mirrored aggregates containing volumes associated with consistency groups to become unmirrored. Similarly, you can modify unmirrored aggregates containing volumes associated with consistency groups to enable mirroring.

Volumes associated and Snapshots associated with consistency groups placed on mirrored aggregates are replicated to the remote site (site B). The contents of the volumes on site B provide a write-order guarantee for the consistency group, allowing you to recover from site B in the event of a disaster. You can access replicated consistency group Snapshots using consistency group Snapshot REST API and System Manager on clusters running ONTAP 9.11.1 or later.

If some or all the volumes associated with a consistency group are located on unmirrored aggregates that are not currently accessible, GET or DELETE operations on the consistency group behave as if the local volumes or hosting aggregates are offline.

### == Consistency group configurations for replication

If site B is running ONTAP 9.10.1 or earlier, only the volumes associated with the consistency groups located on mirrored aggregates are replicated to site B. The consistency group configurations are only replicated to site B, if both sites are running ONTAP 9.11.1 or later. After site B is upgraded to ONTAP 9.11.1, data for consistency groups on site A that have all their associated volumes placed on mirrored aggregates are replicated to site B.

### == Upgrade considerations

Consistency groups created with SM-BC in ONTAP 9.8 and 9.9.1 will automatically be upgraded and become manageable under **Storage > Consistency Groups** in System Manager or the ONTAP REST API when upgrading to ONTAP 9.10.1 or later. For more information about upgrading from ONTAP 9.8 or 9.9.1, see [SM-BC upgrade and revert considerations](#).

Consistency group snapshots ONTAP REST API can be managed through System Manager's Consistency Group interface and through consistency group REST API endpoints.

Snapshots created with the ONTAPI commands `cg-start` and `cg-commit` will not be recognized as consistency group Snapshots and thus cannot be managed through System Manager's consistency group interface or the consistency group endpoints in the ONTAP REST API.

### == Supported features by release

|                                                   | ONTAP<br>9.13.1 | ONTAP<br>9.12.1  | ONTAP<br>9.11.1 | ONTAP<br>9.10.1 |

= Consistency group limits

:icons: font

:relative\_path: ./consistency-groups/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

When planning and managing your consistency groups, account for object limits at the scope of both the cluster and the parent or child consistency group.

If you are using SnapMirror Business Continuity, refer to [SM-BC restrictions and limitations for limits](#).

| Limit                                              | Scope   | Minimum | Maximum                                 |
|----------------------------------------------------|---------|---------|-----------------------------------------|
| Number of consistency groups                       | Cluster | 0       | Same as maximum volume count in cluster |
| Number of parent consistency groups                | Cluster | 0       | Same as maximum volume count in cluster |
| Number of individual and parent consistency groups | Cluster | 0       | Same as maximum volume count in cluster |

|                                                                  |                                         |   |    |
|------------------------------------------------------------------|-----------------------------------------|---|----|
| Consistency group                                                | Same as maximum volume count in cluster | 1 | 80 |
| Number of volumes in the child of a parent consistency group     | Parent consistency group                | 1 | 80 |
| Number of volumes in a child consistency group                   | Child consistency group                 | 1 | 80 |
| Number of child consistency groups in a parent consistency group | Parent consistency group                | 1 | 5  |

= Configure a single consistency group

:icons: font

:relative\_path: ./consistency-groups/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

Consistency groups can be created with existing volumes or new LUNs or volumes (depending on the version of ONTAP). A volume or LUN can only be associated with one consistency group at a time.

### Before you begin

- In ONTAP 9.10.1 through 9.11.1, modifying the member volumes of a consistency group after it is created is not supported.

Beginning in ONTAP 9.12.1, you can modify the member volumes of a consistency group. For more information on this process, refer to [Modify a consistency group](#).

== Create a consistency group with new LUNs or volumes

In ONTAP 9.10.1 through 9.12.1, you can create a consistency group using new LUNs. Beginning in ONTAP 9.13.1, System Manager also supports creating a consistency group with new NVMe namespaces or new NAS volumes. (This is also supported in the ONTAP REST API beginning with ONTAP 9.12.1.)

### Steps

- Select **Storage > Consistency groups**.
- Select **+Add** then select the protocol for your storage object.

In ONTAP 9.10.1 through 9.12.1, the only option for a new storage object is **Using new LUNs**.

Beginning in ONTAP 9.13.1, System Manager supports creating consistency groups with new NVMe namespaces and new NAS volumes.

- Name the consistency group. Designate the number of volumes or LUNs and the capacity per volume or LUN.
  - Application Type:** If you are using ONTAP 9.12.1 or later, select an application type. If no value is selected, the consistency group will be assigned the type of **Other** by default. Learn more about tagging consistency in [Application and component tags](#). If you plan to create a consistency group with a remote protection policy, you must use **Other**.
  - For **New LUNs:** Select the host operating system and LUN format. Enter the host initiator

information.

- c. For **New NAS volumes**: choose the appropriate export option (NFS or SMB/CIFS) based on the NAS configuration of your SVM.
- d. For **New NVMe namespaces**: Select the host operating system and NVMe subsystem.
4. To configure protection policies, add a child consistency group, or access permissions, select **More options**.
5. Select **Save**.
6. Confirm your consistency group has been created by returning to the main consistency group menu where it will appear once the job completes. If you set a protection policy, you will know it has been applied when you see a green shield under look under the appropriate policy, remote or local.

== Create a consistency group with existing volumes

You can use existing volumes to create a consistency group.

### Steps

1. Select **Storage > Consistency groups**.
2. Select **+Add** then **Using existing volumes**.
3. Name the consistency group and select the storage VM.
  - a. **Application Type**: If you are using ONTAP 9.12.1 or later, select an application type. If no value is selected, the consistency group will be assigned the type of **Other** by default. Learn more about tagging consistency in [Application and component tags](#). If the consistency group has an SM-BC relationship, you must use **Other**.
4. Select the existing volumes to include. Only volumes that are not already part of a consistency group will be available for selection.

If creating a consistency group with existing volumes, the consistency group supports FlexVol volumes. Volumes with Asynchronous or Synchronous SnapMirror relationships can be added to consistency groups, but they are not consistency group-aware. Consistency groups do not support S3 buckets, or storage VMs with SVMDR relationships.

5. Select **Save**.

6. Confirm your consistency group has been created by returning to the main consistency group menu where it will appear once the ONTAP job completes. If you have chosen a protection policy, confirm it was properly set by selecting your consistency group from the menu. If you set a protection policy, you will know it has been applied when you see a green shield under look under the appropriate policy, remote or local.

### Next steps

- [Protect a consistency group](#)
- [Modify a consistency group](#)
- [Clone a consistency group](#)

= Configure a hierarchical consistency group

:icons: font

:relative\_path: ./consistency-groups/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..../media/

If your application workload consists of more than one subset of volumes, where each subset is consistent across its own associated volumes, ONTAP enables you to create a hierarchical consistency group.

Hierarchical consistency groups have a parent that can include up to five individual consistency groups. Hierarchical consistency groups can support different local Snapshot policies across consistency groups or individual volumes. If you use a remote protection policy, that will apply for the entire hierarchical consistency group (parent and children).

Beginning in ONTAP 9.13.1, you can [modify the geometry of your consistency groups](#) and [move volumes between child consistency groups](#).

For object limits on consistency groups, see [Object limits for consistency groups](#).

**== Create a hierarchical consistency group with new LUNs or volumes**

When creating a hierarchical consistency group, you can populate it with new LUNs. Beginning in ONTAP 9.13.1, you can also use new NVMe namespaces and NAS volumes.

### Steps

1. Select **Storage > Consistency groups**.
2. Select **+Add** then select the protocol for your storage object.

In ONTAP 9.10.1 through 9.12.1, the only option for a new storage object is **Using new LUNs**.

Beginning in ONTAP 9.13.1, System Manager supports creating consistency groups with new NVMe namespaces and new NAS volumes.

3. Name the consistency group. Designate the number of volumes or LUNs and the capacity per volume or LUN.
  - a. **Application Type:** If you are using ONTAP 9.12.1 or later, select an application type. If no value is selected, the consistency group will be assigned the type of **Other** by default. Learn more about tagging consistency in [Application and component tags](#). If you plan to use a remote protection policy, you must choose **Other**.
4. Select the host operating system and LUN format. Enter the host initiator information.
  - a. For **New LUNs**: Select the host operating system and LUN format. Enter the host initiator information.
  - b. For **New NAS volumes**: choose the appropriate export option (NFS or SMB/CIFS) based on the NAS configuration of your SVM.
  - c. For **New NVMe namespaces**: Select the host operating system and NVMe subsystem.
5. To add a child consistency group, select **More options** then **+Add child consistency group**.
6. Select the performance level, the number of LUNs or volumes, and capacity per LUN or volume. Designate the appropriate export configurations or operating system information based on the protocol you are using.
7. Optionally, select a local snapshot policy and set the access permissions.
8. Repeat for up to five child consistency groups.
9. Select **Save**.
10. Confirm your consistency group has been created by returning to the main consistency group menu where it will appear once the ONTAP job completes. If you set a protection policy, look under the

appropriate policy, remote or local, which should display a green shield with a checkmark in it.

**== Create a hierarchical consistency group with existing volumes**

You can organize existing volumes into a hierarchical consistency group.

## Steps

1. Select **Storage > Consistency groups**.
2. Select **+Add then Using existing volumes**.
3. Select the storage VM.
4. Select the existing volumes to include. Only volumes that are not already part of a consistency group will be available for selection.
5. To add a child consistency group, select **+Add Child Consistency Group**. Create the necessary consistency groups, which will be named automatically.
  - a. **Component Type:** If you are using ONTAP 9.12.1 or later, select a component type of "data", "logs", or "other". If no value is selected, the consistency group will be assigned the type of **Other** by default. Learn more about tagging consistency in [Application and component tags](#). If you plan to use a remote protection policy, you must use **Other**.
6. Assign existing volumes to each consistency group.
7. Optionally, select a local Snapshot policy.
8. Repeat for up to five child consistency groups.
9. Select **Save**.
10. Confirm your consistency group has been created by returning to the main consistency group menu where it will appear once the ONTAP job completes. If you have chosen a protection policy, confirm it was properly set by selecting your consistency group from the menu; under the appropriate policy type, you will see a green shield with a checkmark inside of it.

## Next steps

- [Modify the geometry of a consistency groups](#)
- [Modify a consistency group](#)
- [Protect a consistency group](#)

= Protect a consistency group

:icons: font

:relative\_path: ./consistency-groups/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

:hardbreaks-option:

Consistency groups offer easily managed local and remote protection for SAN, NAS, and NVMe applications that span multiple volumes.

Creating a consistency group does not automatically enable protection. Protection policies can be set at the time of creation or after creating your consistency group. You can protect consistency groups using:

- Local Snapshot policies
- SnapMirror Business Continuity (SM-BC)
- Asynchronous SnapMirror (beginning 9.13.1)

If you are utilizing nested consistency groups, you can set different protection policies for the parent and child consistency groups.

Beginning in ONTAP 9.11.1, consistency groups offer [two-phase consistency group Snapshot creation](#). The two-phase Snapshot executes a precheck, ensuring the Snapshot will be captured successfully.

Recovery can occur for an entire consistency group, a single consistency group in a hierarchical configuration, or for individual volumes within the consistency group. Recovery can be achieved by selecting the consistency group you want to recover from, selecting the Snapshot copy type, and then identifying the Snapshot copy to base the restoration on. For more information about this process, see [Restore a volume from an earlier Snapshot copy](#).

#### == Set a local Snapshot protection policy

Setting a local snapshot protection policy allows you to create a policy spanning all volumes in a consistency group.

#### Steps

1. Select **Storage > Consistency groups**.
2. Select the consistency group you have created from the Consistency group menu.
3. At the top right of the overview page for the consistency group, select **Edit**.
4. Check the box next to **Schedule Snapshot copies (local)**.
5. Select a Snapshot policy. To configure a new, custom policy, refer to [Create a custom data protection policy](#).
6. Select **Save**.
7. Return to the consistency group overview menu. In the left column under **Snapshot Copies (Local)**, the status will say protected next to .

#### == Create two-phase consistency group snapshots

Beginning in ONTAP 9.11.1, consistency groups support two-phase commits for consistency group (CG) Snapshot creation, which execute a precheck before committing the Snapshot. This feature is only available with the ONTAP REST API.

Two-phase CG Snapshot creation is only available for Snapshot creation, not provisioning consistency groups or restoring consistency groups.

A two-phase CG Snapshot creation breaks the Snapshot creation process invoked with a POST request to the `/application/consistency-groups/{consistency_group_uuid}/snapshots` endpoint into a sequence of two phases:

1. In the first phase initiated with a POST request, the API executes prechecks, triggers Snapshot creation, and starts a timer for designated interval.
2. If the POST request in phase one completes with a 201 status code, you can invoke the second phase within the designated interval from the first phase, committing the Snapshot to the appropriate endpoint.

For more information about the ONTAP REST API, refer to the [API reference](#) or visit the [ONTAP REST API page](#) at the NetApp Developer Network for a complete list of API endpoints.

#### Before you begin

- To use two-phase CG Snapshot creation, all nodes in the cluster must be running ONTAP 9.11.1 or later.
- Only one active invocation of a consistency group Snapshot creation operation is supported on a consistency group instance at a time, whether it be a one-phase or two-phase. Attempting to invoke a Snapshot creation while another one is in progress will result in a failure.
- The two-phase consistency group Snapshot creation can be invoked with the `action=start` parameter.

You can additionally use the `action_timeout` parameter to specify the maximum number of seconds that the Snapshot creation process can take.

The `action_timeout` parameter can be set equal to an integer between 5 and 120. The default value of `action_timeout` is 7.

## Steps

1. Invoke the Snapshot creation. Send a POST request to the consistency group endpoint using the `action=start` parameter.

```
curl -k -X POST 'https://<IP_address>/application/consistency-groups/<cg-uuid>/snapshots?action=start&action_timeout=7' -H "accept: application/hal+json" -H "content-type: application/json" -d '
{
 "name": "<snapshot_name>",
 "consistency_type": "crash",
 "comment": "<comment>",
 "snapmirror_label": "<SnapMirror_label>"
}'
```

2. If the POST request succeeds, your output will include a snapshot uuid. Using that uuid, submit a PATCH request to commit the Snapshot.

```
curl -k -X PATCH 'https://<IP_address>/application/consistency-groups/<cg_uuid>/snapshots/<snapshot_id>?action=commit' -H "accept: application/hal+json" -H "content-type: application/json"
```

**== Set remote protection for a consistency group**

Consistency groups offer remote protection through SM-BC and, beginning in ONTAP 9.13.1, asynchronous SnapMirror.

**==== Configure protection with SM-BC**

You can utilize SM-BC to ensure Snapshot copies of consistency groups created on your consistency group are copied to the destination. To learn more about SM-BC, refer to [Configure protection for business continuity](#).

## Before you begin

- SM-BC relationships cannot be established on volumes mounted for NAS access.
- The policy labels in the source and destination cluster must match.
- SM-BC will not replicate Snapshot copies by default unless a rule with a SnapMirror label is added to the predefined `AutomatedFailOver` policy and the Snapshot copies are created with that label.

To learn more about this process, refer to [Configure protection for business continuity](#).

- Beginning in ONTAP 9.13.1, you can non-disruptively [add volumes to a consistency group](#) with an active SM-BC relationship. Any other changes to a consistency group require you to break the SM-BC relationship, modify the consistency group, then reestablish and resynchronize the relationship.

## Steps

1. Ensure you have met the [prerequisites for using SM-BC](#).
2. Select **Storage > Consistency groups**.
3. Select the consistency group you have created from the Consistency group menu.
4. At the top right of the overview page, select **More** then **Protect**.
5. System Manager auto-fills source-side information. Select the appropriate cluster and storage VM for the destination. Select a protection policy. Ensure that **Initialize relationship** is checked.
6. Select **Save**.
7. The consistency group needs to initialize and synchronize. Confirm synchronization has completed successfully by returning to the **Consistency group** menu. The **SnapMirror (Remote)** status displays  Protected next to it.

==> Configure asynchronous SnapMirror protection

Beginning in ONTAP 9.13.1, you can configure asynchronous SnapMirror protection for a single consistency group.

## Before you begin

- Asynchronous SnapMirror protection is only available for single consistency groups. It is not supported for hierarchical consistency groups. To convert a hierarchical consistency group into a single consistency group, see [modify consistency group architecture](#).
- [Cascade deployments](#) are not supported with SM-BC.
- The policy labels in the source and destination cluster must match.
- You can non-disruptively [add volumes to a consistency group](#) with an active asynchronous SnapMirror relationship. Any other changes to a consistency group require you to break the SnapMirror relationship, modify the consistency group, then reestablish and resynchronize the relationship.
- If you have configured an asynchronous SnapMirror protection relationship for multiple individual volumes, you can convert those volumes into a consistency group while retaining the existing Snapshots. To convert volumes successfully:
  - There must be a common Snapshot copy of the volumes.
  - You must break the existing SnapMirror relationship, [add the volumes to a single consistency group](#), then resynchronize the relationship using the following workflow.

## Steps

1. From the destination cluster, select **Storage > Consistency groups**.

2. Select the consistency group you have created from the Consistency group menu.
3. At the top right of the overview page, select **More** then **Protect**.
4. System Manager auto-fills source-side information. Select the appropriate cluster and storage VM for the destination. Select a protection policy. Ensure that **Initialize relationship** is checked.

When selecting an asynchronous policy, you have the option to **Override Transfer Schedule**.

5. Select **Save**.

6. The consistency group needs to initialize and synchronize. Confirm synchronization has completed successfully by returning to the **Consistency group** menu. The **SnapMirror (Remote)** status displays **Protected** next to .

## == Visualize relationships

System Manager visualizes LUN maps under the **Protection > Relationships** menu. When you select a source relationship, System Manager displays a visualization of the source relationships. By selecting a volume, you can delve deeper into these relationships to see a list of the contained LUNs and the initiator group relationships. This information can be downloaded as an Excel workbook from the individual volume view; the download operation will run in the background.

## Related information

- [Clone a consistency group](#)
- [Configure Snapshot copies](#)
- [Create custom data protection policies](#)
- [Recover from Snapshot copies](#)
- [Restore a volume from an earlier Snapshot copy](#)
- [SM-BC overview](#)
- [ONTAP Automation documentation](#)
- [Asynchronous SnapMirror disaster recovery basics](#)

= Modify member volumes in a consistency group

:icons: font

:relative\_path: ./consistency-groups/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

Beginning in ONTAP 9.12.1, you can modify a consistency group by removing volumes or adding existing volumes (expanding the consistency group). Beginning in ONTAP 9.13.1, you can move volumes between child consistency groups if they share a common parent.

## == Add volumes to a consistency group

Beginning in ONTAP 9.12.1, you can non-disruptively add volumes to a consistency group.

### Before you begin

- You cannot add volumes associated with another consistency group.
- Consistency groups support NAS, SAN, and NVMe protocols.

- You can add up to 16 volumes at a time to a consistency group if the adjustments are within the overall [consistency group limits](#).
- Beginning in ONTAP 9.13.1, you can non-disruptively add volumes to a consistency group with an active SnapMirror Business Continuity (SM-BC) or asynchronous SnapMirror protection policy.
- When you add volumes to a consistency group protected by SM-BC, the status of the SM-BC relationship status will change to "Expanding" until mirroring and protection are configured for the new volume. If a disaster occurs on the primary cluster before this process completes, the consistency group reverts back to its original composition as part of the failover operation.
- In ONTAP 9.12.1, you *cannot* add volumes to a consistency group in an SM-BC relationship. You must first break the SM-BC relationship, modify the consistency group, then restore protection with SM-BC.
- Beginning in ONTAP 9.12.1, the ONTAP REST API supports adding *new* or existing volumes to a consistency group. For more information about the ONTAP REST API, refer to [ONTAP REST API reference documentation](#).

Beginning in ONTAP 9.13.1, this functionality is supported in System Manager.

- When expanding a consistency group, Snapshot copies of the consistency group captured before the modification will be considered partial. Any restore operation based on that Snapshot copy will reflect the consistency group at the point-in-time of the snapshot.
- If you are using ONTAP 9.10.1 through 9.11.1, you cannot modify a consistency group. To change the configuration of a consistency group in ONTAP 9.10.1 or 9.11.1, you must delete the consistency group, then create a new consistency group with the volumes you want to include.

## Steps

1. Select **Storage > Consistency groups**.
2. Select the consistency group that you want to modify.
3. If you are modifying a single consistency group, at the top of the **Volumes** menu, select **More** and then **Expand** to add a volume.

If you are modifying a child consistency group, identify the parent consistency group you want to modify. Select the **>** button to view the child consistency groups, then select  next to the name of the child consistency group you want to modify. From that menu, select **Expand**.

4. Select up to 16 volumes to add to the consistency group.
5. Select **Save**. When the operation completes, view the newly added volumes in the consistency group's **Volumes** menu.

**== Remove volumes from a consistency group**

Volumes removed from a consistency group are not deleted. They remain active in the cluster.

## Before you begin

- You cannot remove volumes from a consistency group in a SnapMirror Business Continuity (SM-BC) relationship. You must first break the SM-BC relationship to modify the consistency group and then reestablish the relationship.
- If a consistency group has no volumes in it following the remove operation, the consistency group will be deleted.
- When a volume is removed from a consistency group, existing Snapshots of the consistency group remain but are considered invalid. The existing Snapshots cannot be used to restore the contents of

the consistency group. Volume-granular Snapshots remain valid.

- If you delete a volume from the cluster, it is automatically removed from the consistency group.
- To change the configuration of a consistency group in ONTAP 9.10.1 or 9.11.1, you must delete the consistency group then create a new consistency group with the desired member volumes.
- Deleting a volume from the cluster will automatically remove it the consistency group.

## Steps

1. Select **Storage > Consistency groups**.
2. Select the single or child consistency group that you want to modify.
3. In the **Volumes** menu, select the checkboxes next to the individual volumes you want to remove from the consistency group.
4. Select **Remove volumes from the consistency group**.
5. Confirm that you understand removing the volumes will cause all Snapshot copies of the consistency group to become invalid and select **Remove**.

== Move volumes between consistency groups

Beginning in ONTAP 9.13.1, you can move volumes between child consistency groups that share a parent.

## Before you begin

- You can only move volumes between consistency groups nested under the same parent consistency group.
- Existing consistency group Snapshots become invalid and no longer accessible as consistency group snapshots. Individual volume Snapshots remain valid.
- Snapshot copies of the parent consistency group remain valid.
- If you move all volumes out of a child consistency group, that consistency group will be deleted.
- Modifications to a consistency group must abide by [consistency group limits](#).

## Steps

1. Select **Storage > Consistency groups**.
2. Select the parent consistency group that contains the volumes you want to move. Find the child consistency group and then expand the **Volumes** menu. Select the volumes you want to move.
3. Select **Move**.
4. Choose whether you want to move the volumes to a new consistency group or an existing group.
  - a. To move to an existing consistency group, select **Existing child consistency group** then choose the consistency group's name from the dropdown menu.
  - b. To move to a new consistency group, select **New child consistency group**. Enter a name for the new child consistency group and select a component type.
5. Select **Move**.

## Related information

- [Consistency group limits](#)
- [Clone a consistency group](#)

= Modify consistency group geometry

```
:icons: font
:relative_path: ./consistency-groups/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/
```

Beginning in ONTAP 9.13.1, you can modify the geometry of a consistency group. Modifying the geometry of a consistency group enables you to alter the configuration of child or parent consistency groups without disruption to ongoing IO operations.

Modifying consistency group geometry will have an impact on existing snapshot copies.

You cannot modify the geometry of a consistency group that is configured with a remote protection policy. You must first break the protection relationship, modify the geometry, then restore remote protection.

**== Add a new child consistency group**

Beginning in ONTAP 9.13.1, you can add a new child consistency group to an existing parent consistency group.

#### Before you begin

- A parent consistency group can contain a maximum of five child consistency groups. See [consistency group limits](#) for other limits.
- You cannot add a child consistency group to a single consistency group. You must first [promote](#) the consistency group, then you can add a child consistency group.
- Existing Snapshot copies of the consistency group captured before the expand operation will be considered partial. Any restore operation based on that snapshot copy will reflect the consistency group at the point-in-time of the Snapshot copy.

#### Steps

1. Select **Storage > Consistency groups**.
2. Select the parent consistency group you want to which you want to add a child consistency group.
3. Next to the parent consistency group's name, select **More** then **Add new child consistency group**.
4. Enter a name for your consistency group.
5. Choose whether you would like to add new or existing volumes.
  - a. If you are adding existing volumes, select **Existing volumes** then choose the volumes from the dropdown menu.
  - b. If you are adding new volumes, select **New volumes** then designate the number of volumes and their size.
6. Select **Add**.

**== Detach a child consistency group**

Beginning in ONTAP 9.13.1, you can remove a child consistency group from its parent, converting it into an individual consistency group.

#### Before you begin

- Detaching a child consistency group causes the parent consistency group's snapshots to become invalid and inaccessible. Volume granular snapshots remain valid.

- Existing Snapshot copies of the individual consistency group remain valid.

## Steps

1. Select **Storage > Consistency groups**.
2. Select the parent consistency group that contains the child you want to detach.
3. Next to the child consistency group you want to detach, select **More** then **Detach from parent**.
4. Optionally, rename the consistency group and select an application type.
5. Select **Detach**.

**== Move a single consistency group under a parent consistency group**

Beginning in ONTAP 9.13.1, you can convert an existing single consistency group to a child consistency group. You can either move the consistency group under an existing parent consistency group or create a new parent consistency group during the move operation.

## Before you begin

- The parent consistency group must have four or fewer children. A parent consistency group can contain a maximum of five child consistency groups. See [consistency group limits](#) for other limits.
- Existing snapshot copies of the *parent* consistency group captured before this operation will be considered partial. Any restore operation based on one of those Snapshot copies will reflect the consistency group at the point-in-time of the Snapshot copy.
- Existing consistency group snapshots of the single consistency group remain valid.

## Steps

1. Select **Storage > Consistency groups**.
2. Select the consistency group you want to convert.
3. Select **More** then **Move under different consistency group**.
4. Optionally, enter a new name for the consistency group and select a component type. By default, the component type will be Other.
5. Choose if you want to migrate to an existing parent consistency group or create a new parent consistency group:
  - a. To migrate to an existing parent consistency group, select **Existing consistency group** then choose the consistency group from the dropdown menu.
  - b. To create a new parent consistency group, select **New consistency group** then provide a name for the new consistency group.
6. Select **Move**.

**== Promote a child consistency group**

Beginning in ONTAP 9.13.1, you can promote a single consistency group to a parent consistency group. When you promote the single consistency group to a parent, you also create a new child consistency group that inherits all of the volumes in the original, single consistency group.

## Before you begin

- If you want to convert a child consistency group to a parent consistency group, you must first [detach](#) the child consistency group then follow this procedure.
- Existing Snapshot copies of the consistency group remain valid after you promote the consistency

group.

## Steps

1. Select **Storage > Consistency groups**.
2. Select the consistency group you want to promote.
3. Select **More** then **Promote to parent consistency group**.
4. Enter a **Name** and select a **Component type** for the child consistency group.
5. Select **Promote**.

== Demote a parent to a single consistency group

Beginning in ONTAP 9.13.1, you can demote a parent consistency group to a single consistency group. Demoting the parent flattens the hierarchy of the consistency group, removing all associated child consistency groups. All volumes in the consistency group will remain under the new, single consistency group.

## Before you begin

- Existing Snapshot copies of the parent consistency group remain valid after you demote it to a single consistency. Existing Snapshot copies of any of the associated child consistency groups of that parent will become invalid, but the individual volume snapshots within them continue to be accessible as volume-granular Snapshots.

## Steps

1. Select **Storage > Consistency groups**.
2. Select the parent consistency group you want to demote.
3. Select **More** then **Demote to single consistency group**.
4. A warning will advise you that all associated child consistency groups will be deleted and their volumes will be moved under the new, single consistency group. Select **Demote** to confirm you understand the impact.

= Clone a consistency group

:icons: font

:relative\_path: ./consistency-groups/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

Beginning in ONTAP 9.12.1, you can clone a consistency group to create a copy of a consistency group and its contents. Cloning a consistency group creates a copy of the consistency group configuration, its metadata such as application type, and all the volumes and its contents such as files, directories, LUNs or NVMe namespaces.

When cloning a consistency group, you can clone it with its current configuration, but with volume contents as they are or based on an existing consistency group Snapshot.

Cloning a consistency group is supported only for the entire consistency group. You cannot clone an individual child consistency group in a hierarchical relationship: only the complete consistency group configuration can be cloned.

When you clone a consistency group, the following components are not cloned:

- iGroups

- LUN maps
- NVMe subsystems
- NVMe namespace subsystem maps

## Before you begin

- When you clone a consistency group, ONTAP will not create SMB shares for the cloned volumes if a share name is not specified. \* Cloned consistency groups are not mounted if a junction path is not specified.
- If you attempt to clone a consistency group based on a Snapshot that does not reflect the consistency group's current configuration, the operation will fail.
- After you clone a consistency group, you need to perform the appropriate mapping operation.

Refer to [Map igroups to multiple LUNs](#) or [Map an NVMe namespace to a subsystem](#) for more information.

- Cloning a consistency group is not supported for a consistency group in a SnapMirror Business Continuity relationship or with any associated DP volumes.

## Steps

1. Select **Storage > Consistency groups**.
2. Select the consistency group you want to clone from the **Consistency Group** menu.
3. At the top right of the overview page for the consistency group, select **Clone**.
4. Enter a name for the new, cloned consistency group or accept the default name.
  - a. Choose if you want to enable [Thin Provisioning](#).
  - b. Choose **Split Clone** if you want to dissociate the consistency group from its source and allocate additional disk space for the cloned consistency group.
5. To clone the consistency group in its current state, choose **Add a new Snapshot copy**.

To clone the consistency group based on a snapshot, choose **Use an existing Snapshot copy**. Selecting this option will open a new sub-menu. Choose the Snapshot that you want to use as the basis for the clone operation.

6. Select **Clone**.
7. Return to the **Consistency Group** menu to confirm your consistency group has been cloned.

## Next steps

- [Map igroups to multiple LUNs](#)
- [Map an NVMe namespace to a subsystem](#)

= Delete a consistency group

:icons: font

:relative\_path: ./consistency-groups/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

If you decide that you no longer need a consistency group, you can delete it.

Deleting a consistency group deletes the instance of the consistency group and does **not** impact the constituent volumes or LUNs. Deleting a consistency group does not result in deletion of the Snapshots

present on each volume, but they will no longer be accessible as consistency group Snapshots. They can, however, continue to be managed as ordinary volume granular snapshots.

Consistency groups will be deleted if all of the volumes in the consistency group are deleted.

If you are using a version of ONTAP between 9.10.1 to 9.12.0, volumes can only be removed from a consistency group if the volume itself is deleted, in which case the volume is automatically removed from the consistency group. Beginning in ONTAP 9.12.1, you can remove volumes from a consistency group without deleting. For more information on this process, refer to [Modify a consistency group](#).

## Steps

1. Select **Storage > Consistency groups**.
2. Select the consistency group you would like to delete.
3. Next to the name of the consistency group, select  and then **Delete**.

= SnapMirror Business Continuity

= Overview

:hardbreaks:

:icons: font

:linkatrrs:

:relative\_path: ./smbc/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

Beginning with ONTAP 9.8, you can use SnapMirror Business Continuity (SM-BC) to protect applications with LUNs, enabling applications to fail over transparently, ensuring business continuity in case of a disaster. SM-BC is supported on AFF clusters (including AFF C-Series) or All SAN Array (ASA) clusters, where the primary and secondary clusters can be either AFF or ASA. SM-BC protects applications with iSCSI or FCP LUNs.

== Benefits

SnapMirror Business Continuity provides the following benefits:

- Provides continuous availability for business-critical applications
- Ability to host critical applications alternately from primary and secondary site
- Simplified application management using consistency groups for dependent write-order consistency
- The ability to test failover for each application
- Instantaneous creation of mirror clones without impacting application availability
- Beginning in ONTAP 9.11.1, SM-BC supports [single-file SnapRestore](#).

== Typical use cases

==== Application deployment for zero RTO or Transparent Application Failover

Transparent Application Failover is based on host multipath I/O (MPIO) software-based path failover to achieve non-disruptive access to the storage. Both LUN copies, for example, primary(L1P) and mirror copy(L1S), have the same identity (serial number) and are reported as read-writable to the host. However, reads and writes are serviced only by the primary volume. I/Os issued to the mirror copy are

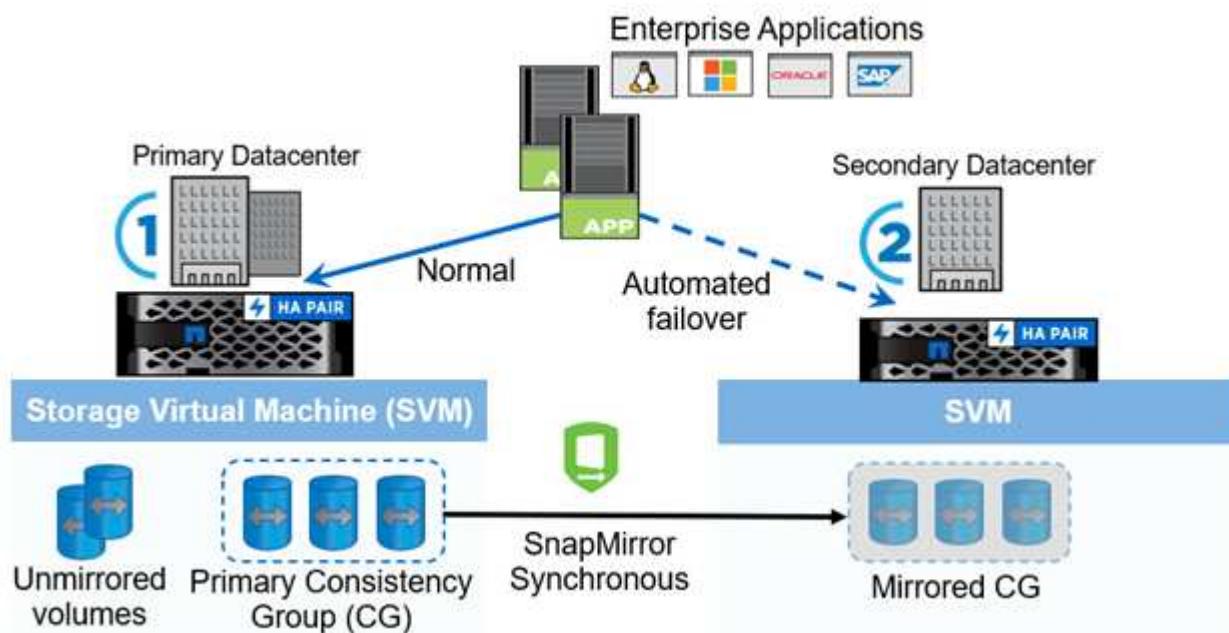

proxied to the primary copy. The host's preferred path to L1 is VS1:N1 based on Asymmetric Logical Unit Access (ALUA) access state Active Optimized (A/O). Mediator is recommended as part of the deployment, primarily to perform failover in case of a storage outage on the primary.

### == Disaster scenario

The site hosting the primary cluster experiences a disaster. Host multipathing software marks all paths through the cluster as down and uses paths from the secondary cluster. The result is a non-disruptive failover to the mirror copy for LUN L1. L1S is converted from a mirror copy to an active copy of LUN L1. The failover happens automatically when an external Mediator is configured. The host's preferred path to L1 becomes VS2:N1.

### == Architecture

The following figure illustrates the operation of the SnapMirror Business Continuity feature at a high level.

### = Key concepts

:hardbreaks:

:icons: font

:linkatrrs:

:relative\_path: ./smbc/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/./media/

As you begin to explore the ONTAP SnapMirror Business Continuity and plan a deployment, it is helpful to become familiar with the key terminology and concepts.

### SM-BC

Acronym for the SnapMirror Business Continuity (SM-BC) solution available with ONTAP 9.8 and later.

### Consistency group

Beginning with ONTAP 9.10.1, consistency groups have become a first-order management unit. To learn more about consistency groups, refer to [Consistency groups overview](#).

A consistency group (CG) is a collection of FlexVol volumes that provide a write order consistency guarantee for the application workload which needs to be protected for business continuity. The purpose of a consistency group is to take simultaneous crash-consistent Snapshot copies of a collection of volumes at a point in time. In regular deployment, the group of volumes picked to be part of a CG are mapped to an application instance. SnapMirror relationships, also known as a CG relationship, is established between a source CG and a destination CG. The source and destination CGs must contain the same number and type of volumes.

### **Constituent**

The individual FlexVol volumes that are part of a consistency group.

### **Mediator**

ONTAP Mediator provides an alternate health path to the peer cluster, with the intercluster LIFs providing the other health path. With the Mediator's health information, clusters can differentiate between intercluster LIF failure and site failure. When the site goes down, Mediator passes on the health information to the peer cluster on demand, facilitating the peer cluster to fail over. With the Mediator-provided information and the intercluster LIF health check information, ONTAP determines whether to perform an auto failover, if it is failover incapable, continue or stop.

Mediator is one of three parties in the SM-BC quorum, working with the primary cluster and the secondary cluster to reach a consensus. A consensus requires at least two parties in the quorum to agree to an operation.

### **Out of Sync (OOS)**

The application I/O is not replicating to the secondary storage system. The destination volume is not in sync with the source volume because SnapMirror replication is not occurring. If the mirror state is Snapmirrored, this indicates a transfer failure or failure due to an unsupported operation.

### **Zero RPO**

Zero recovery point objective. This is the acceptable amount of data loss from downtime.

### **Zero RTO**

Zero recovery time objective or Transparent Application Failover is achieved by using host multipath I/O (MPIO) software-based path failover to provide non-disruptive access to the storage.

### **Planned failover**

A manual operation to change the roles of copies in a SM-BC relationship. The primary becomes the secondary and the secondary becomes the primary. ALUA reporting also changes.

### **Automatic unplanned failover (AUFO)**

An automatic operation to perform a failover to the mirror copy. The operation requires assistance from Mediator to detect that the primary copy is unavailable.

= Planning

= Prerequisites

:hardbreaks:

:icons: font

:linkatrrs:

:relative\_path: ./smbc/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

There are several prerequisites that you should consider as part of planning a

## SnapMirror Business Continuity solution deployment.

### == Hardware

- Only two-node HA clusters are supported
- Both clusters must be either AFF or ASA (no mixing)

### == Software

\* ONTAP 9.8 or later

\* ONTAP Mediator 1.2 or later

\* A Linux server or virtual machine for the ONTAP Mediator running one of the following:

| ONTAP Mediator version | Supported Linux versions                                                                                                                                     |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.6                    | <ul style="list-style-type: none"><li>• Red Hat Enterprise Linux: 8.4, 8.5, 8.6, 8.7, 9.0, 9.1</li><li>• Rocky Linux 8 and 9</li></ul>                       |
| 1.5                    | <ul style="list-style-type: none"><li>• Red Hat Enterprise Linux: 7.6, 7.7, 7.8, 7.9, 8.1, 8.2, 8.3, 8.4, 8.5</li><li>• CentOS: 7.6, 7.7, 7.8, 7.9</li></ul> |
| 1.4                    | <ul style="list-style-type: none"><li>• Red Hat Enterprise Linux: 7.6, 7.7, 7.8, 7.9, 8.1, 8.2, 8.3, 8.4, 8.5</li><li>• CentOS: 7.6, 7.7, 7.8, 7.9</li></ul> |
| 1.3                    | <ul style="list-style-type: none"><li>• Red Hat Enterprise Linux: 7.6, 7.7, 7.8, 7.9, 8.1, 8.2, 8.3</li><li>• CentOS: 7.6, 7.7, 7.8, 7.9</li></ul>           |
| 1.2                    | <ul style="list-style-type: none"><li>• Red Hat Enterprise Linux: 7.6, 7.7, 7.8, 8.1</li><li>• CentOS: 7.6, 7.7, 7.8</li></ul>                               |

### == Licensing

- SnapMirror synchronous (SM-S) license must be applied on both clusters
- SnapMirror license must be applied on both clusters

If your ONTAP storage systems were purchased before June 2019, click [NetApp ONTAP Master License Keys](#) to get the required SM-S license.

### == Networking environment

- Inter-cluster latency round trip time (RTT) must be less than 10 milliseconds
- SCSI-3 persistent reservations are **not** supported with SM-BC

### == Supported protocols

- Only SAN protocols are supported (not NFS/SMB)
- Only Fibre Channel and iSCSI protocols are supported

- The default IPspace is required by SM-BC for cluster peer relationships. Custom IPspace is not supported.

## == NTFS Security Style

NTFS security style is **not** supported on SM-BC volumes.

## == ONTAP Mediator

- Must be provisioned externally and attached to ONTAP for transparent application failover.
- For more information about the ONTAP Mediator, see [Prepare to install the ONTAP Mediator service](#).

## == Read-write destination volumes

- SM-BC relationships are not supported on read-write destination volumes. Before you can use a read-write volume, you must convert it to a DP volume by creating a volume-level SnapMirror relationship and then deleting the relationship. For details, see [Converting existing relationships to SM-BC relationships](#)

## == Large LUNs and large volumes

- Large LUNs and large volumes greater than 100TB are supported only on All SAN Arrays

You must ensure that both the primary and secondary cluster are All SAN Arrays, and that they both have ONTAP 9.8 or later installed. If the secondary cluster is running a version earlier than ONTAP 9.8 or if it is not an All SAN Array, the synchronous relationship can go out of sync if the primary volume grows larger than 100 TB.

## = Considerations and limits

:hardbreaks:

:icons: font

:linkatrrs:

:relative\_path: ./smbc/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..../media/

There are several considerations, restrictions, and limitations to consider using the SnapMirror Business Continuity solution.

## == Object limits

### ==== Consistency groups in a cluster

Consistency group limits for a cluster with SM-BC are calculated based on relationships and depend on the version of ONTAP used. Limits are platform-independent.

| ONTAP version          | Maximum number of relationships |
|------------------------|---------------------------------|
| ONTAP 9.8-9.9.1        | 5                               |
| ONTAP 9.10.1           | 20                              |
| ONTAP 9.11.1 and later | 50                              |

### ==== Volumes per consistency group

From ONTAP 9.8 to 9.9.1, the maximum number of volumes supported per SM-BC consistency group relationship is twelve, a limit which is platform-independent. Beginning with ONTAP 9.10.1, the maximum number of volumes supported per SM-BC relationship is sixteen.

#### ==== Volumes

Limits in SM-BC are calculated based on the number of endpoints, not the number of relationships. A consistency group with 12 volumes contributes 12 endpoints on both the source and destination. Both SM-BC and SnapMirror Synchronous relationships contribute to the total number of endpoints.

The maximum endpoints per platform are included in the following table.

| S. No | Platform | Endpoints per HA for SM-BC |              |                        | Overall sync and SM-BC endpoints per HA |              |                        |
|-------|----------|----------------------------|--------------|------------------------|-----------------------------------------|--------------|------------------------|
|       |          | ONTAP 9.8-9.9.1            | ONTAP 9.10.1 | ONTAP 9.11.1 and later | ONTAP 9.8-9.9.1                         | ONTAP 9.10.1 | ONTAP 9.11.1 and later |
| 1     | AFF      | 60                         | 200          | 400                    | 80                                      | 200          | 400                    |
| 2     | ASA      | 60                         | 200          | 400                    | 80                                      | 200          | 400                    |

#### ==== SAN object limits

The following SAN object limits are included in the following table and apply regardless of the platform.

| Limits of objects in an SM-BC relationship                           | Count |
|----------------------------------------------------------------------|-------|
| LUNs per volume                                                      | 256   |
| LUN maps per node                                                    | 2048  |
| LUN maps per cluster                                                 | 4096  |
| LIFs per VServer (with at least one volume in an SM-BC relationship) | 256   |
| Inter-cluster LIFs per node                                          | 4     |
| Inter-cluster LIFs per cluster                                       | 8     |

#### == Supported configurations and features

SM-BC is supported with numerous operating systems and ONTAP features, including:

- AIX (beginning ONTAP 9.11.1)
- Fan-out configurations
- HP-UX (beginning ONTAP 9.10.1)
- NDMP copy (beginning ONTAP 9.13.1)
- Partial file restore (beginning ONTAP 9.12.1)
- Solaris 11.4 (beginning ONTAP 9.10.1)

#### ==== AIX

Beginning with ONTAP 9.11.1, AIX is supported with SM-BC. With an AIX configuration, the primary

cluster is the "active" cluster.

In an AIX configuration, failovers are disruptive. With each failover, you will need to perform a re-scan on the host for I/O operations to resume.

To configure for AIX host with SM-BC, refer to the Knowledge Base article [How to configure an AIX host for SnapMirror Business Continuity \(SM-BC\)](#).

#### ==== HP-UX known issues and limitations for SM-BC configuration

Beginning in ONTAP 9.10.1, SM-BC for HP-UX is supported. If an automatic unplanned failover (AUFO) event occurs on the isolated master cluster in the SM-BC configuration, it might take more than 120 seconds for I/O to resume on the HP-UX host. Depending on the applications that are running, this might not lead to any I/O disruption or error messages. If an AUFO event on the isolated master cluster occurs, you must restart applications on the HP-UX host that have a disruption tolerance of less than 120 seconds.

An AUFO event on the isolated master cluster might cause dual event failure when the connection between the primary and the secondary cluster is lost and the connection between the primary cluster and the mediator is also lost. This is considered a rare event, unlike other AUFO events.

#### ==== FabricPool

SM-BC supports source and destination volumes on FabricPool aggregates with the tiering policy of None, Snapshot or Auto. SM-S SM-BC does not support FabricPool aggregates using a tiering policy of All.

#### ==== Fan-out configurations

SM-BC supports [fan-out configurations](#) with the `MirrorAllSnapshots` policy and, beginning in ONTAP 9.11.1, the `MirrorAndVault` policy. Fan-out configurations are not supported in SM-BC with the `XDPDefault` policy.

If you experience a failover on the SM-BC destination in a fan-out configuration, you will have to manually [resume protection in the fan-out configuration](#).

#### ==== NDMP restore

Beginning in ONTAP 9.13.1, you can use NDMP to copy and restore data with SM-BC. Using NDMP allows you to move data onto the SM-BC source to complete a restore without pausing protection. This is particularly useful in fan-out configurations.

To learn more about this process, see [Transfer data using ndmp copy](#).

#### ==== Partial file restore

Beginning in ONTAP 9.12.1, partial LUN restore is supported for SM-BC volumes. For information on this process, refer to [Restore part of a file from a Snapshot copy](#).

#### ==== Solaris Host setting recommendation for SM-BC configuration

Beginning with ONTAP 9.10.1, SM-BC supports Solaris 11.4. To ensure the Solaris client applications are non-disruptive when an unplanned site failover switchover occurs in an SM-BC environment, you must configure the Solaris 11.4 Host with the `f_tpgs` parameter.

Follow these steps to configure the override parameter:

1. Create configuration file /etc/driver/drv/scsi\_vhci.conf with an entry similar to the following for the NetApp storage type connected to the host:

```
scsi-vhci-failover-override =
"NETAPP LUN", "f_tpgs"
```

2. Use devprop and mdb commands to verify the override has been successfully applied:

```
root@host-A:~# devprop -v -n /scsi_vhci scsi-vhci-failover-override
scsi-vhci-failover-override=NETAPP LUN + f_tpgs
root@host-A:~# echo "*scsi_vhci_dip::print -x struct dev_info
devi_child | ::list struct dev_info devi_sibling| ::print struct
dev_info devi_mdi_client| ::print mdi_client_t ct_vprivate| ::print
struct scsi_vhci_lun svl_lun_wwn svl_fops_name" | mdb -k`
```

```
svl_lun_wwn = 0xa002a1c8960 "600a098038313477543f524539787938"
svl_fops_name = 0xa00298d69e0 "conf f_tpgs"
```

conf will be added to the svl\_fops\_name when a scsi-vhci-failover-override has been applied.

For additional information and recommended changes to default settings, refer to NetApp KB article [Solaris Host support recommended settings in SnapMirror Business Continuity \(SM-BC\) configuration](#).

= ONTAP access options  
:hardbreaks:  
:icons: font  
:linkatrs:  
:relative\_path: ./smbc/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You have several access options available when configuring the ONTAP nodes participating in an SM- BC deployment. You should select the option that best matches your specific environment and deployment goals.

In all cases, you must sign in using the administrator account with a valid password.

### Command line interface

The text-based command line interface is available through the ONTAP management shell. You can access the CLI using secure shell (SSH).

## System Manager

You can connect to the System Manager using a modern web browser. The web GUI provides an intuitive and easy-to-use interface when accessing the SnapMirror Business Continuity functionality. For more information about using System Manager, see [System Manager documentation](#).

## REST API

The ONTAP REST API exposed to external clients provides another option when connecting to the ONTAP. You can access the API using any mainstream programming language or tool that supports REST web services. Popular choices include:

- Python (including the ONTAP Python client library)
- Java
- Curl

Using a programming or scripting language provides an opportunity to automate the deployment and management of a SnapMirror Business Continuity deployment. For more information, see the ONTAP online documentation page at your ONTAP storage system.

= Prepare to use the ONTAP CLI

```
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/
```

You should be familiar with the following commands when deploying the SnapMirror Business Continuity solution using the ONTAP command line interface.

SM-BC does not support the snapmirror quiesce and snapmirror resume commands for relationships with active sync policy.

For more information about the following ONTAP commands, see [NetApp Documentation: ONTAP 9](#).

| Command               | Description                                    |
|-----------------------|------------------------------------------------|
| lun igroup create     | Create an igroup on a cluster                  |
| lun map               | Map a LUN to an igroup                         |
| lun show              | Display a list of LUNs                         |
| snapmirror create     | Create a new SnapMirror relationship           |
| snapmirror initialize | Initialize an SM-BC consistency group          |
| snapmirror update     | Initiates a common snapshot creation operation |
| snapmirror show       | Display a list of SnapMirror relationships     |
| snapmirror failover   | Start a planned failover operation             |
| snapmirror resync     | Start a resynchronization operation            |
| snapmirror delete     | Delete a SnapMirror relationship               |

| Command                      | Description                                                                                  |
|------------------------------|----------------------------------------------------------------------------------------------|
| snapmirror release           | Remove source information for a SnapMirror relationship                                      |
| volume snapshot restore-file | Available with SM-BC beginning in ONTAP 9.11.1, <a href="#">restore a single file or LUN</a> |

= Prepare to use the ONTAP Mediator

:hardbreaks:

:icons: font

:linkatrrs:

:relative\_path: ./smbc/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

The ONTAP Mediator establishes a quorum for the ONTAP clusters in an SM-BC relationship. It coordinates automated failover when a failure is detected and helps to avoid split-brain scenarios when each cluster simultaneously tries to establish control as the primary cluster.

## == Prerequisites for the ONTAP Mediator

The ONTAP Mediator includes its own set of prerequisites. You must meet these prerequisites before installing the mediator. For more information, see [Prepare to install the ONTAP Mediator service](#).

## == Network configuration

By default, the ONTAP Mediator provides service through TCP port 31784. You should make sure that port 31784 is open and available between the ONTAP clusters and the mediator.

= Summary of deployment best practices

:hardbreaks:

:icons: font

:linkatrrs:

:relative\_path: ./smbc/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

There are several best practices that you should consider as part of planning an SnapMirror Business Continuity deployment.

## == SAN

The SnapMirror Business Continuity solution supports only SAN workloads. You should follow the SAN best practices in all cases.

In addition:

- Replicated LUNs in the secondary cluster must be mapped to the host and the I/O paths to the LUNs from both the primary and secondary cluster must be discovered at the time of host configuration.
- After an out of sync (OOS) event exceeds 80 seconds, or after an automatic unplanned failover, it is important to rescan the host LUN I/O path to ensure that there is no I/O path loss. For more information, see the respective host OS vendor's documentation on rescan of LUN I/O paths.

## == Mediator

To be fully functional and to enable automatic unplanned failover, the external ONTAP mediator should be provisioned and configured with ONTAP clusters.

When installing the mediator, you should replace the self-signed certificate with a valid certificate signed by a mainstream reliable CA.

## == SnapMirror

You should terminate an SnapMirror relationship in the following order:

1. Perform `snapmirror delete` at the destination cluster
2. Perform `snapmirror release` at the source cluster

= Manage SnapMirror for Business Continuity using System Manager

= Configure Mediator

```
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ../
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/../encryption-at-rest/../media/
```

Use System Manager to configure the Mediator server to be used for automated failover. You can also replace the self-signed SSL and CA with the third party validated SSL Certificate and CA if you have not already done so.

### Steps

1. Navigate to **Protection > Overview > Mediator > Configure**.
2. Click **Add**, and enter the following Mediator server information:
  - IPv4 address
  - Username
  - Password
  - Certificate

= Configure protection for business continuity

```
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ../
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/../encryption-at-rest/../media/
```

Configuring protection for business continuity involves selecting LUNs on the ONTAP source cluster and adding them to a consistency group. Open System Manager from a browser on the source cluster to begin configuring protection for business

continuity.

This workflow is designed for ONTAP 9.8 and 9.9. Beginning with ONTAP 9.10.1, it is recommended that you begin by creating a consistency group and then use SM-BC as a remote protection.

## == About this task

- LUNs must reside on the same storage VM.
- LUNs can reside on different volumes.
- The source and destination cluster cannot be the same.
- The default IPspace is required by SM-BC for cluster peer relationships. Custom IPspace is not supported.

## Steps

1. Choose the LUNs you want to protect and add them to a protection group: **Protection > Overview > Protect for Business Continuity > Protect LUNs**.
2. Select one or more LUNs to protect on the source cluster.
3. Select the destination cluster and SVM.
4. **Initialize relationship** is selected by default. Click **Save** to begin protection.
5. Go to **Dashboard > Performance** to verify IOPS activity for the LUNs.
6. On the destination cluster, use System Manager to verify that the protection for business continuity relationship is in sync: **Protection > Relationships**.

= Reestablish the original protection relationship after an unplanned failover

```
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ../media/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/../encryption-at-rest/
```

ONTAP uses the ONTAP Mediator to detect when a failure occurs on the primary storage system and executes automatic unplanned failover to the secondary storage system. You can use System Manager to reverse the relationship and reestablish the original protection relationship when original source cluster is back online.

## Steps

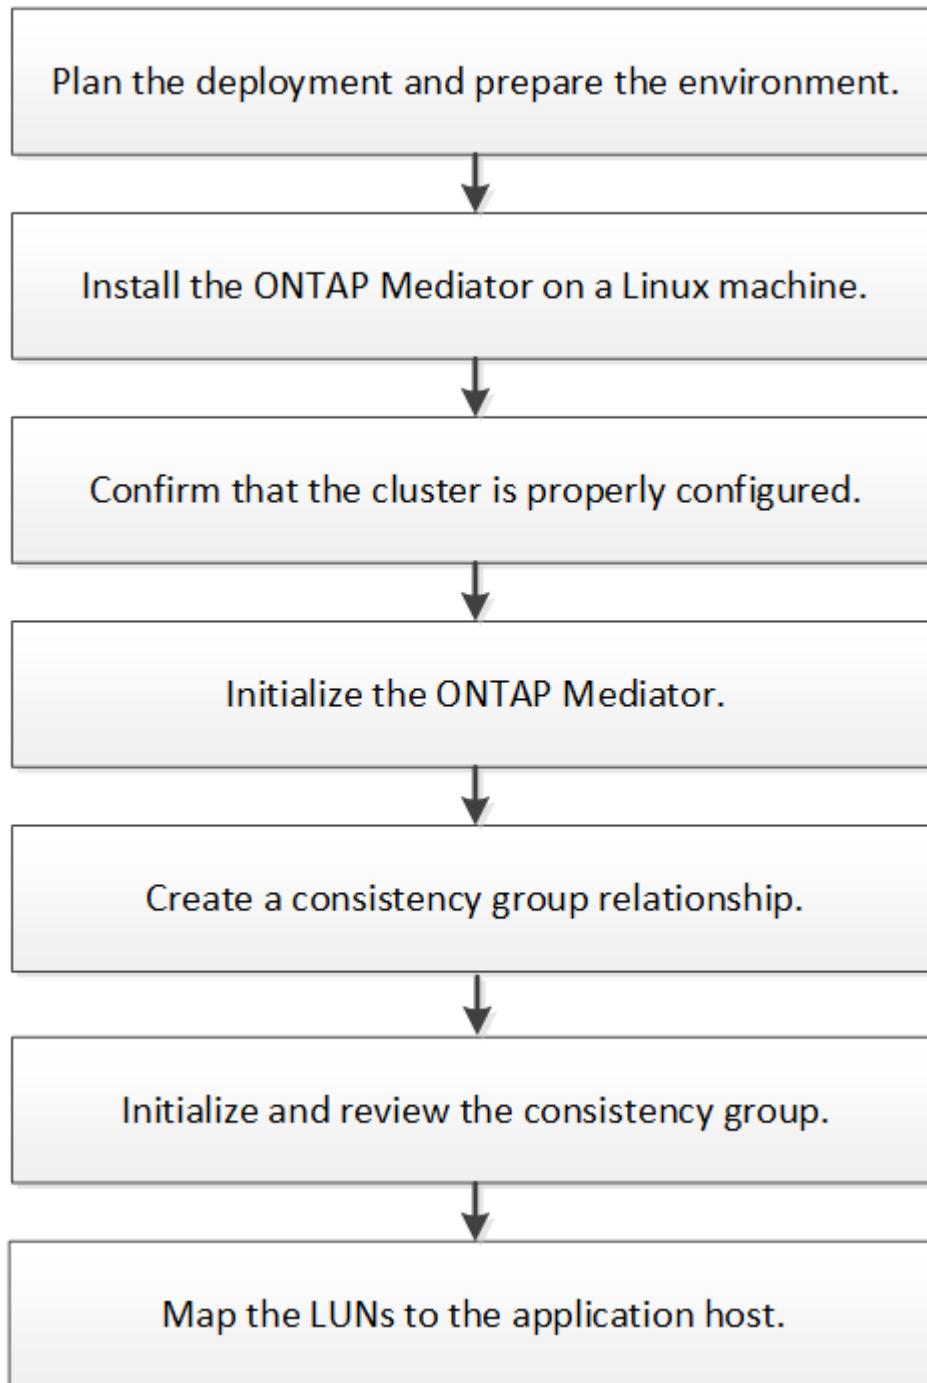

1. Navigate to **Protection > Relationships** and wait for the relationship state to show “InSync.”
2. To resume operations on the original source cluster, click  and select **Failover**.

= Installation and setup using the ONTAP CLI

= High level deployment workflow

```
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/../encryption-at-rest/
```

You can use the following workflow to install and implement the SnapMirror Business Continuity solution.

= Install ONTAP Mediator Service and confirm the ONTAP cluster configuration  
:hardbreaks:  
:icons: font  
:linkatrrs:  
:relative\_path: ./smbc/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You should make sure that your source and destination clusters are configured properly.

## About this task

Proceed through each of the following steps. For each step, you should confirm that the specific configuration has been performed. Use the link included after each step to get more information as needed.

## Steps

1. Install the ONTAP Mediator service before you ensure that your source and destination clusters are configured properly.

### [ONTAP Mediator service](#)

2. Confirm that a cluster peering relationship exists between the clusters.

The default IPspace is required by SM-BC for cluster peer relationships. Custom IPspace is not supported.

### [Configure peer relationships](#)

3. Confirm that the Storage VMs are created on each cluster.

### [Creating an SVM](#)

4. Confirm that a peer relationship exists between the Storage VMs on each cluster.

### [Creating an SVM peering relationship](#)

5. Confirm that the volumes exist for your LUNs.

### [Creating a volume](#)

6. Confirm that at least one SAN LIF is created on each node in the cluster.

### [Considerations for LIFs in a cluster SAN environment](#)

### [Creating a LIF](#)

7. Confirm that the necessary LUNs are created and mapped to igroup, which is used to map LUNs to the initiator on the application host.

### [Create LUNs and map igroups](#)

8. Rescan the application host to discover any new LUNs.

= Initialize the ONTAP Mediator

:hardbreaks:

:icons: font

:linkatrrs:

:relative\_path: ./smbc/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You must initialize Mediator on one of your cluster peers before SM-BC can perform planned and automatic unplanned failover operations.

## About this task

You can initialize Mediator from either cluster. When you issue the `mediator add` command on one cluster, Mediator is automatically added on the other cluster.

## Steps

1. Initialize Mediator on one of the clusters:

```
snapmirror mediator add -mediator-address IP_Address -peer-cluster
cluster_name -username user_name
```

### Example

```
cluster1::> snapmirror mediator add -mediator-address 192.168.10.1
-peer-cluster cluster2 -username mediatoradmin
Notice: Enter the mediator password.

Enter the password: *****
Enter the password again: *****
```

2. Check the status of the Mediator configuration:

```
snapmirror mediator show
```

| Mediator Address | Peer Cluster | Connection Status | Quorum Status |
|------------------|--------------|-------------------|---------------|
| 192.168.10.1     | cluster-2    | connected         | true          |

-quorum-status indicates whether the SnapMirror consistency group relationships are synchronized with Mediator.

= Create a consistency group relationship

:hardbreaks:

:icons: font

:linkatrrs:

:relative\_path: ./smbc/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

You must create a SM-BC consistency group which also establishes the synchronous consistency group relationship.

This workflow applies to users in ONTAP 9.8 and 9.9.1. If using these ONTAP CLI commands beginning with ONTAP 9.10.1, they will still work to create a consistency group, however, it is recommended that you manage consistency groups with System Manager or the ONTAP REST API.

## Before you begin

The following prerequisites and restrictions apply:

- You must be a cluster or storage VM administrator
- You must have a SnapMirror Synchronous license
- The destination volumes must be type DP
- The primary and the secondary storage VM must be in a peered relationship
- All constituent volumes in a consistency group must be in a single Storage VM
- You cannot establish SM-BC consistency group relationships across ASA clusters and non-ASA clusters
- The name of the consistency group must be unique

### About this task

You must create the consistency group relationship from the destination cluster. You can map up to 12 constituents using the `cg-item-mappings` parameter on the `snapmirror create` command.

### Steps

1. Create a consistency group and constituent relationship. This example creates two consistency groups: `cg_src` with constituent volumes `vol1` and `vol2`, and `cg_dist` with constituent volumes `vol1_dr` and `vol2_dr`.

```
destination::> snapmirror create -source-path vs1_src:/cg/cg_src
-destination-path vs1_dst:/cg/cg_dst -cg-item-mappings
vol_src1:@vol_dst1,vol_src2:@vol_dst2 -policy AutomatedFailOver
```

= Initialize a consistency group

```
:hardbreaks:
:icons: font
:linkattrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/
```

After creating a consistency group, you must initialize it.

This workflow applies to users in ONTAP 9.8 and 9.9.1. If using these ONTAP CLI commands beginning with ONTAP 9.10.1, they will still work to initialize a consistency group, however, it is recommended that you manage consistency groups with System Manager or the ONTAP REST API.

### Before you begin

You must be a cluster or storage VM administrator.

### About this task

You initialize the consistency group from the destination cluster.

### Steps

1. Sign in to the ONTAP CLI at the destination cluster and initialize the consistency group:

```
destination::>snapmirror initialize -destination-path vs1_dst:/cg/cg_dst
```

2. Confirm that the initialization operation completed successfully. The status should be `InSync`.

```
snapmirror show
```

= Mapping LUNs to the application hosts  
:hardbreaks:  
:icons: font  
:linkatrrs:  
:relative\_path: ./smbc/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You must create an igroup on each cluster so you can map LUNs to the initiator on the application host.

### About this task

You should perform this configuration on both the source and destination clusters.

### Steps

1. Create an igroup on each cluster:

```
lun igrup create -igroup name -protocol fcp|iscsi -ostype os -initiator
initiator_name
```

#### Example

```
lun igrup create -igroup ig1 -protocol iscsi -ostype linux
-initiator -initiator iqn.2001-04.com.example:abc123
```

2. Map LUNs to the igroup:

```
lun map -path path_name -igroup igrup_name
```

#### Example:

```
lun map -path /vol/src1/11 -group ig1
```

3. Verify the LUNs are mapped:

```
lun show
```

4. On the application host, discover the new LUNs.

= Administration

= Create a common Snapshot copy  
:hardbreaks:  
:icons: font  
:linkatrrs:  
:relative\_path: ./smbc/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

In addition to the regularly scheduled Snapshot copy operations, you can manually create a common Snapshot copy between the volumes in the primary SnapMirror consistency group and the volumes in the secondary SnapMirror consistency group.

In ONTAP 9.8, the scheduled snapshot creation interval is one hour. Beginning with ONTAP 9.9.1, that interval is 12 hours.

### Before you begin

The SnapMirror group relationship must be in sync.

### Steps

1. Create a common Snapshot copy:

```
destination::>snapmirror update -destination-path vs1_dst:/cg/cg_dst
```

2. Monitor the progress of the update:

```
destination::>snapmirror show -fields -newest-snapshot
```

= Perform a planned failover

:hardbreaks:

:icons: font

:linkatrrs:

:relative\_path: ./smbc/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can perform a planned failover to test your disaster recovery configuration or to perform maintenance on the primary cluster.

### Before you begin

- The relationship must be in sync
- Nondisruptive operations must not be running
- The ONTAP Mediator must be configured, connected, and in quorum

### About this task

A planned failover is initiated by the administrator of the secondary cluster. The operation requires switching the primary and secondary roles so that the secondary cluster takes over from the primary. The new primary cluster can then begin processing input and output requests locally without disrupting client operations.

### Steps

1. Start the failover operation:

```
destination::>snapmirror failover start -destination-path
vs1_dst:/cg/cg_dst
```

2. Monitor the progress of the failover:

```
destination::>snapmirror failover show
```

3. When the failover operation is complete, you can monitor the Synchronous SnapMirror protection

relationship status from the destination:

```
destination::>snapmirror show
```

```
= Automatic unplanned failover operations
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/
```

An automatic unplanned failover (AUFO) operation occurs when the primary cluster is down or isolated. When this occurs, the secondary cluster is converted to the primary and begins serving clients. This operation is performed only with assistance from the ONTAP Mediator.

After the automatic unplanned failover, it is important to rescan the host LUN I/O paths so that there is no loss of I/O paths.

You can monitor the status of the automatic unplanned failover by using the `snapmirror failover show` command.

```
= Basic monitoring
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/
```

There are several SM-BC components and operations you can monitor.

**== ONTAP mediator**

During normal operation, the Mediator state should be connected. If it is in any other state, this might indicate an error condition. You can review the [Event Management System \(EMS\) messages](#) to determine the error and appropriate corrective actions.

**== Planned failover operations**

You can monitor status and progress of a planned failover operation using the `snapmirror failover show` command. For example:

```
ClusterB::> snapmirror failover start -destination-path vs1:/cg/dcg1
```

Once the failover operation is complete, you can monitor the Synchronous SnapMirror protection status from the new destination cluster. For example:

```
ClusterA::> snapmirror show
```

Refer to the [EMS reference](#) to learn about event messages and corrective actions.

## == Automatic unplanned failover operations

During an unplanned automatic failover, you can monitor the status of the operation using the snapmirror failover show command. For example:

```
ClusterB::> snapmirror failover show -instance
Start Time: 9/23/2020 22:03:29
 Source Path: vs1:/cg/scg3
 Destination Path: vs3:/cg/dcg3
 Failover Status: completed
 Error Reason:
 End Time: 9/23/2020 22:03:30
 Primary Data Cluster: cluster-2
 Last Progress Update: -
 Failover Type: unplanned
 Error Reason codes: -
```

Refer to the [EMS reference](#) to learn about event messages and about corrective actions.

## == SM-BC availability

You can check the availability of the SM-BC relationship using a series of commands, either on the primary cluster, the secondary cluster, or both.

Commands you use include the snapmirror mediator show command on both the primary and secondary cluster to check the connection and quorum status, the snapmirror show command, and the volume show command. For example:

```

SMBC_A::*> snapmirror mediator show
Mediator Address Peer Cluster Connection Status Quorum Status

10.236.172.86 SMBC_B connected true

SMBC_B::*> snapmirror mediator show
Mediator Address Peer Cluster Connection Status Quorum Status

10.236.172.86 SMBC_A connected true

SMBC_B::*> snapmirror show -expand

Progress
Source Destination Mirror Relationship Total
Last
Path Type Path State Status Progress Healthy
Updated

-
vs0:/cg/cg1 XDP vs1:/cg/cg1_dp Snapmirrored InSync - true
-
vs0:vol1 XDP vs1:vol1_dp Snapmirrored InSync - true
-
2 entries were displayed.

SMBC_A::*> volume show -fields is-smbc-master,smbc-consensus,is-smbc-failover-capable -volume vol1
vserver volume is-smbc-master is-smbc-failover-capable smbc-consensus

vs0 vol1 true false Consensus

SMBC_B::*> volume show -fields is-smbc-master,smbc-consensus,is-smbc-failover-capable -volume vol1_dp
vserver volume is-smbc-master is-smbc-failover-capable smbc-consensus

vs1 vol1_dp false true No-consensus

```

= Add and remove volumes in a consistency group

:hardbreaks:  
:icons: font  
:linkatrrs:  
:relative\_path: ./smbc/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

Adding and removing volumes in an active SM-BC relationship depends on the version of ONTAP you are using.

## About this task

In ONTAP 9.8 through 9.9.1, you can add or remove volumes to a consistency group using the ONTAP CLI.

Beginning with ONTAP 9.10.1, it is recommended that you manage [consistency groups](#) through System Manager or with the ONTAP REST API. If you want to change the composition of the consistency group by adding or removing a volume, you must first delete the original relationship and then create the consistency group again with the new composition.

Beginning in ONTAP 9.13.1, you can non-disruptively add volumes to a consistency group with an active SM-BC relationship from the source or destination.

Removing volumes from a consistency group with an SM-BC relationship is disruptive and you must break the SnapMirror relationship before proceeding with this operation.

## Before you begin

- The composition change is not allowed when the consistency group is in the “InSync” state.
- The destination volume should be of type DP.
- The new volume you add to expand the consistency group must have a pair of common Snapshot copies between the source and destination volumes.

## Steps

This procedure assumes that there are two volume mappings: vol\_src1 ↔ vol\_dst1 and vol\_src2 ↔ vol\_dst2, in a consistency group relationship between the end points vs1\_src:/cg/cg\_src and vs1\_dst:/cg/cg\_dst.

1. Verify that a common Snapshot copy exists between the source and destination volumes on both the source and destination cluster:

```
source::>snapshot show -vserver vs1_src -volume vol_src3 -snapshot snapmirror*
destination::>snapshot show -vserver vs1_dst -volume vol_dst3 -snapshot snapmirror*
```

2. If no common Snapshot copy exists, create and initialize a FlexVol SnapMirror relationship:

```
destination::>snapmirror initialize -source-path vs1_src:vol_src3 -destination-path vs1_dst:vol_dst3
```

3. Delete the zero RTO consistency group relationship:

```
destination::>snapmirror delete -destination-path vs1_dst:vol_dst3
```

4. Release the source SnapMirror relationship and retain the common Snapshot copies:

```
source::>snapmirror release -relationship-info-only true -destination-path vs1_dst:vol_dst3
```

5. Unmap the LUNs and delete the existing consistency group relationship:

```
destination::>lun mapping delete -vserver vs1_dst -path <lun_path> -igroup
```

```
<igroup_name>
```

The destination LUNs are unmapped, while the LUNs on the primary copy continue to serve the host I/O.

```
destination::>snapmirror delete -destination-path vs1_dst:/cg/cg_dst
source::>snapmirror release -destination-path vs1_dst:/cg/cg_dst -relationship
-info-only true
```

6. If you are using ONTAP 9.10.1 through 9.13.0, delete and recreate and the consistency group on the source with the correct composition. Follow the steps in [Delete a consistency group](#) and then [Configure a single consistency group](#). In ONTAP 9.10.1 and later, you must perform the delete and create operations in System Manager or with the ONTAP REST API; there is no CLI procedure.

If you are using ONTAP 9.8, 9.0, or 9.9.1, skip to the next step.

7. Create the new consistency group on the destination with the new composition:

```
destination::>snapmirror create -source-path vs1_src:/cg/cg_src -destination
-path vs1_dst:/cg/cg_dst -cg-item-mappings vol_src1:@vol_dst1,
vol_src2:@vol_dst2, vol_src3:@vol_dst3
```

8. Resynchronize the zero RTO consistency group relationship to ensure it is in sync:

```
destination::>snapmirror resync -destination-path vs1_dst:/cg/cg_dst
```

9. Remap the LUNs that you unmapped in Step 5:

```
destination::>lun map -vserver vs1_dst -path lun_path -igroup igrup_name
```

10. Rescan host LUN I/O paths to restore all paths to the LUNs.

Beginning in ONTAP 9.13.1, you can non-disruptively add volumes to a consistency group with an active SM-BC relationship. SM-BC supports adding volumes from both the source or destination.

For details on adding volumes from the source consistency group, see [Modify a consistency group](#).

#### Add a volume from the destination cluster

1. On the destination cluster, select **Protection > Relationships**.
2. Find the SM-BC relationship you want to add volumes to. Select then **Expand**.
3. Select the volume relationships whose volumes are to be added to consistency group
4. Select **Expand**.

= Resume protection in a fan-out configuration with SM-BC  
:icons: font  
:relative\_path: ./smbc/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/  
:hardbreaks-option:

SM-BC supports [fan-out configurations](#). Your source volume can be mirrored to an SM-BC destination endpoint and to one or more asynchronous SnapMirror relationships.

Fan-out configurations are supported with the `MirrorAllSnapshots` policy, and, beginning with ONTAP 9.11.1, the `MirrorAndVault` policy. Beginning in ONTAP 9.11.1, fan-out configurations in SM-BC are not supported with the `XDPDefault` policy.

If you experience a failover on the SM-BC destination, the asynchronous SnapMirror destination will become unhealthy, and you must manually restore protection by deleting and recreating the relationship with the asynchronous SnapMirror endpoint.

#### Resume protection in a fan-out configuration

1. Verify the failover has completed successfully:

```
snapmirror failover show
```

2. On the asynchronous Snapmirror endpoint, delete the fan-out endpoint:

```
snapmirror delete -destination-path destination_path
```

3. On the third site, create an asynchronous SnapMirror relationships between the new SM-BC primary volume and the async fan-out destination volume:

```
snapmirror create -source-path source_path -destination-path
destination_path -policy MirrorAllSnapshots -schedule schedule
```

4. Resynchronize the relationship:

```
SnapMirror resync -destination-path destination_path
```

5. Verify the relationship status and health:

```
snapmirror show
```

= Convert existing relationships to SM-BC relationships

:hardbreaks:  
:icons: font  
:linkatrrs:  
:relative\_path: ./smbc/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You can convert an existing zero recovery point protection (zero RPO) Synchronous SnapMirror relationship to an SM-BC zero RTO Synchronous SnapMirror consistency group relationship.

#### Before you begin

- A zero RPO Synchronous SnapMirror relationship exists between the primary and secondary.
- All LUNs on the destination volume are unmapped before the zero RTO SnapMirror relationship is created.

- SM-BC only supports SAN protocols (not NFS/CIFS). Ensure no constituent of the consistency group is mounted for NAS access.

## About this task

- You must be a cluster and SVM administrator on the source and destination.
- You cannot convert zero RPO to zero RTO sync by changing the SnapMirror policy.
- If existing LUNs on the secondary volume are mapped, `snapmirror create` with `AutomatedFailover` policy triggers an error.  
You must ensure the LUNs are unmapped before issuing the `snapmirror create` command.

## Steps

1. Perform a SnapMirror update operation on the existing relationship:

```
destination::>snapmirror update -destination-path vs1_dst:vol1
```

2. Verify that the SnapMirror update completed successfully:

```
destination::>snapmirror show
```

3. Quiesce each of the zero RPO synchronous relationships:

```
destination::>snapmirror quiesce -destination-path vs1_dst:vol1
```

```
destination::>snapmirror quiesce -destination-path vs1_dst:vol2
```

4. Delete each of the zero RPO synchronous relationships:

```
destination::>snapmirror delete -destination-path vs1_dst:vol1
```

```
destination::>snapmirror delete -destination-path vs1_dst:vol2
```

5. Release the source SnapMirror relationship but retain the common Snapshot copies:

```
source::>snapmirror release -relationship-info-only true -destination-path
vs1_dst:vol1
```

```
source::>snapmirror release -relationship-info-only true -destination-path
vs1_dst:vol2
```

6. Create a group zero RTO Synchronous Snapmirror relationship:

```
destination::> snapmirror create -source-path vs1_src:/cg/cg_src
-destination-path vs1_dst:/cg/cg_dst -cg-item-mappings
vol1:@vol1,vol2:@vol2 -policy AutomatedFailover
```

7. Resynchronize the zero RTO consistency group:

```
destination::> snapmirror resync -destination-path vs1_dst:/cg/cg_dst
```

8. Rescan host LUN I/O paths to restore all paths to the LUNs.

= SM-BC upgrade and revert considerations

```
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/
```

You should be aware of the requirements for upgrading and reverting an SM-BC configuration.

## == Upgrade

Before you can configure and use SM-BC, you must upgrade all nodes on the source and destination clusters to ONTAP 9.8 or later.

xref:/encryption-at-rest/Upgrading software on ONTAP clusters

SM-BC is not supported with mixed ONTAP 9.7 and ONTAP 9.8 clusters.

Upgrading clusters from 9.8 or 9.9.1 to 9.10.1 creates new consistency groups on both source and destination for SM-BC relationships.

## == Reverting to ONTAP 9.9.1 from ONTAP 9.10.1

To revert relationships from 9.10.1 to 9.9.1, SM-BC relationships must be deleted, followed by the 9.10.1 consistency group instance. Consistency groups cannot be deleted with an active SMBC relationship. Any FlexVol volumes that were upgraded to 9.10.1 previously associated with another Smart Container or Enterprise App in 9.9.1 or earlier will no longer be associated on revert. Deleting consistency groups does not delete the constituent volumes or volume granular snapshots. Refer to [Delete a consistency group](#) for more information on this task.

## == Reverting to ONTAP 9.7 from ONTAP 9.8

When you revert from ONTAP 9.8 to ONTAP 9.7, you must be aware of the following:

- If the cluster is hosting an SM-BC destination, reverting to ONTAP 9.7 is not allowed until the relationship is broken and deleted.
- If the cluster is hosting an SM-BC source, reverting to ONTAP 9.7 is not allowed until the relationship is released.
- All user-created custom SM-BC SnapMirror policies must be deleted before reverting to ONTAP 9.7.

## Steps

1. Perform a revert check from one of the clusters in the SM-BC relationship:

```
cluster::>*> system node revert-to -version 9.7 -check-only
```

Example:

```
cluster::>*> system node revert-to -version 9.7 -check-only
Error: command failed: The revert check phase failed. The following
issues must be resolved before revert can be completed. Bring the
data LIFs down on running vservers. Command to list the running
vservers: vserver show -admin-state running Command to list the data
```

LIFs that are up: network interface show -role data -status-admin up  
Command to bring all data LIFs down: network interface modify {-role data} -status-admin down  
Disable snapshot policies.  
    Command to list snapshot policies: "snapshot policy show".  
    Command to disable snapshot policies: "snapshot policy modify -vserver \* -enabled false"  
  
    Break off the initialized online data-protection (DP) volumes and delete  
    Uninitialized online data-protection (DP) volumes present on the local node.  
    Command to list all online data-protection volumes on the local node:  
        volume show -type DP -state online -node <local-node-name>  
        Before breaking off the initialized online data-protection volumes,  
        quiesce and abort transfers on associated SnapMirror relationships and  
        wait for the Relationship Status to be Quiesced.  
        Command to quiesce a SnapMirror relationship: snapmirror quiesce  
        Command to abort transfers on a SnapMirror relationship:  
            snapmirror  
            abort  
        Command to see if the Relationship Status of a SnapMirror relationship  
        is Quiesced: snapmirror show  
        Command to break off a data-protection volume: snapmirror break  
        Command to break off a data-protection volume which is the destination  
        of a SnapMirror relationship with a policy of type "vault":  
            snapmirror  
            break -delete-snapshots  
        Uninitialized data-protection volumes are reported by the "snapmirror  
        break" command when applied on a DP volume.  
        Command to delete volume: volume delete  
  
Delete current version snapshots in advanced privilege level.  
    Command to list snapshots: "snapshot show -fs-version 9.8"  
    Command to delete snapshots: "snapshot prepare-for-revert -node <nodename>"  
  
Delete all user-created policies of the type active-strict-sync-

```

mirror
 and active-sync-mirror.

The command to see all active-strict-sync-mirror and active-sync-
mirror
type policies is:
snapmirror policy show -type
active-strict-sync-mirror,active-sync-mirror

The command to delete a policy is :
snapmirror policy delete -vserver <SVM-name> -policy <policy-
name>

```

For information on reverting clusters, see [Revert ONTAP](#).

= Remove an SM-BC configuration

:hardbreaks:

:icons: font

:linkatrrs:

:relative\_path: ./smbc/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can remove zero RTO Synchronous SnapMirror protection and delete the SM-BC relationship configuration.

#### About this task

Before you delete the SM-BC relationship, all LUNs in the destination cluster must be unmapped.

After the LUNs are unmapped and the host is rescanned, the SCSI target notifies the hosts that the LUN inventory has changed. The existing LUNs on the zero RTO secondary volumes change to reflect a new identity after the zero RTO relationship is deleted. Hosts discover the secondary volume LUNs as new LUNs that have no relationship to the source volume LUNs.

The secondary volumes remain DP volumes after the relationship is deleted. You can issue the snapmirror break command to convert them to read/write.

Deleting the relationship is not allowed in the failed-over state when the relationship is not reversed.

#### Steps

1. Delete the SM-BC consistency group relationship between the source endpoint and destination endpoint:

```
Destination::>snapmirror delete -destination-path vs1_dst:/cg/cg_dst
```

2. From the source cluster, release the consistency group relationship and the Snapshot copies created for the relationship:

```
Source::>snapmirror release -destination-path vs1_dst:/cg/cg_dst
```

3. Perform a host rescan to update the LUN inventory.
4. Beginning with ONTAP 9.10.1, deleting the SnapMirror relationship does not delete the consistency group. If you want to delete the consistency group, you must use System Manager or the ONTAP REST API. See [Delete a consistency group](#) for more information.

= Remove ONTAP Mediator

```
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/./media/
```

If you want to remove an existing ONTAP Mediator configuration from your ONTAP clusters, you can do so by using the `snapmirror mediator remove` command.

### Steps

1. Remove ONTAP Mediator:

```
snapmirror mediator remove -mediator-address 12.345.678.90 -peer-cluster
cluster_xyz
```

= Troubleshooting

= SnapMirror delete operation fails in takeover state

```
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/./media/
```

### Issue:

When ONTAP 9.9.1 is installed on a cluster, executing the `snapmirror delete` command fails when an SM-BC consistency group relationship is in takeover state.

### Example:

```
C2_cluster::> snapmirror delete vs1:/cg/dd

Error: command failed: RPC: Couldn't make connection
```

### Solution

When the nodes in an SM-BC relationship are in takeover state, perform the SnapMirror delete and release operation with the "-force" option set to true.

## Example:

```
C2_cluster::> snapmirror delete vs1:/cg/dd -force true

Warning: The relationship between source "vs0:/cg/ss" and destination
 "vs1:/cg/dd" will be deleted, however the items of the
destination
 Consistency Group might not be made writable, deletable, or
modifiable
 after the operation. Manual recovery might be required.

Do you want to continue? {y|n}: y
Operation succeeded: snapmirror delete for the relationship with
destination "vs1:/cg/dd".
```

= Failure creating a SnapMirror relationship and initializing consistency group

:hardbreaks:

:icons: font

:linkattrs:

:relative\_path: ./smbc/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

## Issue:

Creation of SnapMirror relationship and consistency group initialization fails.

## Solution:

Ensure that you have not exceeded the limit of consistency groups per cluster. Consistency group limits in SM-BC are platform independent and differ based on the version of ONTAP. See [Additional restrictions and limitations](#) for limitations based on ONTAP version.

## Error:

If the consistency group is stuck initializing, check the status of your consistency group initializations with the ONTAP REST API, System Manager or the command `sn show -expand`.

## Solution:

If consistency groups fail to initialize, remove the SM-BC relationship, delete the consistency group, then recreate the relationship and initialize it. This workflow differs depending on the version of ONTAP you are using.

| If you are using ONTAP 9.8-9.9.1                                                                                                                                                              | If you are using ONTAP 9.10.1 or later                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ol style="list-style-type: none"><li>1. Remove the SM-BC configuration</li><li>2. Create a consistency group relationship</li><li>3. Initialize the consistency group relationship</li></ol> | <ol style="list-style-type: none"><li>1. Under <b>Protection &gt; Relationships</b>, find the SM-BC relationship on the consistency group. Select  , then <b>Delete</b> to remove the SM-BC relationship.</li><li>2. <a href="#">Delete the consistency group</a></li><li>3. <a href="#">Configure the consistency group</a></li></ol> |

= Planned failover unsuccessful

```
:hardbreaks:
:icons: font
:linkatrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/./media/
```

**Issue:**

After executing the snapmirror failover start command, the output for the snapmirror failover show command displays a message indicates that a nondisruptive operation is in progress.

**Example:**

```
Cluster1::> snapmirror failover show
Source Destination Error
Path Path Type Status start-time end-time Reason
----- ----- ----- -----

vs1:/cg/cg vs0:/cg/cg planned failed 10/1/2020 10/1/2020 SnapMirror
Failover cannot start because a volume move is running. Retry the
command once volume move has finished.
08:35:04
08:35:04
```

**Cause:**

Planned failover cannot begin when a nondisruptive operation is in progress, including volume move, aggregate relocation, and storage failover.

**Solution:**

Wait for the nondisruptive operation to complete and try the failover operation again.

```
= Mediator not reachable or Mediator quorum status is false
:hardbreaks:
:icons: font
:linkatrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/./media/
```

**Issue:**

After executing the snapmirror failover start command, the output for the snapmirror failover show command displays a message indicating that Mediator is not configured.

See [Initialize the ONTAP Mediator](#).

**Example:**

```
Cluster1::> snapmirror failover show
Source Destination Error
Path Path Type Status start-time end-time Reason

vs0:/cg/cg vs1:/cg/cg planned failed 10/1/2020 10/1/2020 SnapMirror
failover cannot start because the source-side precheck failed. reason:
Mediator not configured.
05:50:42 05:50:43
```

**Cause:**

Mediator is not configured or there are network connectivity issues.

**Solution:**

If Mediator is not configured, you must configure Mediator before you can establish an SM-BC relationship. Fix any network connectivity issues. Make sure Mediator is connected and quorum status is true on both the source and destination site using the snapmirror mediator show command.

**Example:**

```
cluster::> snapmirror mediator show
Mediator Address Peer Cluster Connection Status Quorum Status

10.234.10.143 cluster2 connected true
```

= Automatic unplanned failover not triggered on Site B

:hardbreaks:

:icons: font

:linkatrs:

:relative\_path: ./smbc/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

**Issue:**

A failure on Site A does not trigger an unplanned failover on Site B.

**Possible cause #1:**

Mediator is not configured. To determine if this is the cause, issue the snapmirror mediator show command on the Site B cluster.

**Example:**

```
Cluster2::*> snapmirror mediator show
This table is currently empty.
```

This example indicates that Mediator is not configured on Site B.

**Solution:**

Ensure that Mediator is configured on both clusters, that the status is connected, and quorum is set to True.

**Possible cause #2:**

SnapMirror consistency group is out of sync. To determine if this is the cause, view the event log to view if the consistency group was in sync during the time at which the Site A failure occurred.

**Example:**

```
cluster::*> event log show -event *out.of.sync*
```

| Time               | Node               | Severity | Event                                                                                                                                                                                                                                                             |
|--------------------|--------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10/1/2020 23:26:12 | sti42-vsim-ucs511w | ERROR    | sms.status.out.of.sync: Source volume "vs0:zrto_cg_556844_511u_RW1" and destination volume "vs1:zrto_cg_556881_511w_DP1" with relationship UUID "55ab7942-03e5-11eb-ba5a-005056a7dc14" is in "out-of-sync" status due to the following reason: "Transfer failed." |

**Solution:**

Complete the following steps to perform a forced failover on Site B.

1. Unmap all LUNs belonging to the consistency group from Site B.
2. Delete the SnapMirror consistency group relationship using the `force` option.
3. Enter the `snapmirror break` command on the consistency group constituent volumes to convert volumes from DP to R/W, to enable I/O from Site B.
4. Boot up the Site A nodes to create a zero RTO relationship from Site B to Site A.
5. Release the consistency group with `relationship-info-only` on Site A to retain common Snapshot copy and unmap the LUNs belonging to the consistency group.
6. Convert volumes on Site A from R/W to DP by setting up a volume level relationship using either the Sync policy or Async policy.
7. Issue the `snapmirror resync` to synchronize the relationships.
8. Delete the SnapMirror relationships with the Sync policy on Site A.
9. Release the SnapMirror relationships with Sync policy using `relationship-info-only true` on Site B.
10. Create a consistency group relationship from Site B to Site A.
11. Perform a consistency group resync from Site A, and then verify that the consistency group is in sync.
12. Rescan host LUN I/O paths to restore all paths to the LUNs.

= Link between Site B and Mediator down and Site A down

:hardbreaks:

:icons: font

:linkatrrs:

:relative\_path: ./smbc/

```
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/
```

To check on the connection of the Mediator, use the snapmirror mediator show command. If the connection status is unreachable and Site B is unable to reach Site B, you will have an output similar to the one below. Follow the steps in the solution to restore connection

**Example:**

```
cluster::*> snapmirror mediator show
Mediator Address Peer Cluster Connection Status Quorum Status

10.237.86.17 C1_cluster unreachable true
SnapMirror consistency group relationship status is out of sync.

Authentication

C1_cluster 1-80-000011 Unavailable ok
```

**Solution**

Force a failover to enable I/O from Site B and then establish a zero RTO relationship from Site B to Site A.

Complete the following steps to perform a forced failover on Site B.

1. Unmap all LUNs belonging to the consistency group from Site B.
2. Delete the SnapMirror consistency group relationship using the force option.
3. Enter the snapmirror break command on the consistency group constituent volumes to convert volumes from DP to RW, to enable I/O from Site B.
4. Boot up the Site A nodes to create a zero RTO relationship from Site B to Site A.
5. Release the consistency group with relationship-info-only on Site A to retain common Snapshot copy and unmap the LUNs belonging to the consistency group.
6. Convert volumes on Site A from RW to DP by setting up a volume level relationship using either Sync policy or Async policy.
7. Issue the snapmirror resync to synchronize the relationships.
8. Delete the SnapMirror relationships with Sync policy on Site A.
9. Release the SnapMirror relationships with Sync policy using relationship-info-only true on Site B.
10. Create a consistency group relationship from Site B to Site A.
11. Perform a consistency group resync from Site A, and then verify that the consistency group is in sync.
12. Rescan host LUN I/O paths to restore all paths to the LUNs.

= Link between Site A and Mediator down and Site B down

:hardbreaks:

:icons: font

:linkatrrs:

:relative\_path: ./smbc/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/./media/

When using SM-BC, you may lose connectivity between the mediator or your peered clusters. You can diagnose the issue by checking the connection, availability, and consensus status of the different parts of the SM-BC relationship and then forcefully resuming connection.

**Table 3. Determining the cause**

| What to check                        | CLI command                                    | Indicator                                              |
|--------------------------------------|------------------------------------------------|--------------------------------------------------------|
| Mediator from Site A                 | snapmirror mediator show                       | The connection status will be unreachable              |
| Site B connectivity                  | cluster peer show                              | Availability will be unavailable                       |
| Consensus status of the SM-BC volume | volume show volume_name -fields smbc-consensus | The sm-bc consensus field will read Awaiting-consensus |

For additional information about diagnosing and resolving this issue, refer to the Knowledge Base article [Link between Site A and Mediator down and Site B down when using SM-BC](#).

= SM-BC SnapMirror delete operation fails when fence is set on destination volume

:hardbreaks:

:icons: font

:linkatrrs:

:relative\_path: ./smbc/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/./media/

**Issue:**

SnapMirror delete operation fails when any of the destination volumes have redirection fence set.

**Solution**

Performing the following operations to retry the redirection and remove the fence from the destination volume.

- SnapMirror resync
- SnapMirror update

= Volume move operation stuck when primary is down

:hardbreaks:

:icons: font

:linkatrrs:

:relative\_path: ./smbc/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

**Issue:**

A volume move operation is stuck indefinitely in cutover deferred state when the primary site is down in an SM-BC relationship.

When the primary site is down, the secondary site performs an automatic unplanned failover (AUFO). When a volume move operation is in progress when the AUFO is triggered the volume move becomes stuck.

**Solution:**

Abort the volume move instance that is stuck and restart the volume move operation.

= SnapMirror release fails when unable to delete Snapshot copy

:hardbreaks:

:icons: font

:linkatrrs:

:relative\_path: ./smbc/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

**Issue:**

The SnapMirror release operation fails when the Snapshot copy cannot be deleted.

**Solution:**

The Snapshot copy contains a transient tag. Use the `snapshot delete` command with the `-ignore-owners` option to remove the transient Snapshot copy.

```
snapshot delete -volume <volume_name> -snapshot <snapshot_name> -ignore-owners true -force true
```

Retry the `snapmirror release` command.

= Volume move reference Snapshot copy shows as the newest

:hardbreaks:

:icons: font

:linkatrrs:

:relative\_path: ./smbc/

```
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/
```

#### Issue:

After performing a volume move operation on a consistency group volume, the volume move reference Snapshot copy might display as the newest for the SnapMirror relationship.

You can view the newest Snapshot copy with the following command:

```
snapmirror show -fields newest-snapshot status -expand
```

#### Solution:

Manually perform a `snapmirror resync` or wait for the next automatic resync operation after the volume move operation completes.

= Mediator service for MetroCluster and SnapMirror Business Continuity

= ONTAP Mediator overview

:icons: font

:relative\_path: ./mediator/

```
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/
```

The ONTAP Mediator provides several functions for ONTAP features:

- Provides a persistent and fenced store for HA metadata.
- Serves as a ping proxy for controller liveness.
- Provides synchronous node health query functionality to aid in quorum determination.

The ONTAP Mediator provides two additional systemctl services:

- **`ontap_mediator.service`**

Maintains the REST APIs server for managing the ONAP relationships.

- **`mediator-scst.service`**

Controls the startup and shutdown of the iSCSI module (SCST).

== Tools provided for the system administrator

Tools provided for the system administrator:

- **`/usr/local/bin/mediator_change_password`**

Sets a new API password when the current API username and password are provided.

- **`/usr/local/bin/mediator_change_user`**

Sets a new API username when the current API username and password are provided.

- **`/usr/local/bin/mediator_generate_support_bundle`**

Generates a local tgz file containing all useful support information needed for communication with NetApp customer support. This includes application configuration, logs, and some system information. The bundles are generated on the local disk and can be transferred manually, as needed. Storage location: /opt/netapp/data/support\_bundles/

- **/usr/local/bin/uninstall\_ontap\_mediator**

Removes the ONTAP Mediator package and the SCST kernel module. This includes all configuration, logs, and mailbox data.

- **/usr/local/bin/mediator\_unlock\_user**

Releases a lock-out on the API user account if the authentication retry limit was reached. This feature is used to prevent brute force password derivation. It prompts the user for the correct username and password.

- **/usr/local/bin/mediator\_add\_user**

(Support only) Used to add the API user upon installation.

## == Special Notes

ONTAP Mediator relies on SCST to provide iSCSI (See <http://scst.sourceforge.net/index.html>). This package is a kernel module that is compiled during installation specifically for the kernel. Any updates to the kernel might require SCST to be re-installed. Alternatively, uninstall then re-install the ONTAP Mediator, then reconfigure the ONTAP relationship.

Any updates to the server OS kernel should be coordinated with a maintenance window in ONTAP.

## = What's new with the ONTAP Mediator

:icons: font

:relative\_path: ./mediator/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

New enhancements to the ONTAP Mediator are provided with each release. Here's what's new.

## == Enhancements

| ONTAP Mediator version | Enhancements                                                                                                                                                                                                                       |

|                     |     |     |     |     |     |     |     |
|---------------------|-----|-----|-----|-----|-----|-----|-----|
| RHEL 8.5            | No  | No  | No  | No  | Yes | Yes | Yes |
| RHEL 8.6            | No  | No  | No  | No  | No  | No  | Yes |
| RHEL 8.7            | No  | No  | No  | No  | No  | No  | Yes |
| RHEL 9.0            | No  | No  | No  | No  | No  | No  | Yes |
| RHEL 9.1            | No  | No  | No  | No  | No  | No  | Yes |
| CentOS 8 and stream | N/A | N/A | N/A | No  | No  | No  | No  |
| Rocky Linux 8       | N/A | N/A | N/A | N/A | N/A | N/A | Yes |
| Rocky Linux 9       | N/A | N/A | N/A | N/A | N/A | N/A | Yes |

- OS refers to both RedHat and CentOS releases unless otherwise specified.
- "Implied" means that the OS was released after the ONTAP Mediator was shipped, but support has been confirmed.
- "No" means that the OS and ONTAP Mediator are not compatible.
- Centos 8 was removed for all releases due to its rebranching. Centos Stream was deemed as not a suitable production target OS. No support is planned.
- ONTAP Mediator 1.5 was the last supported release for RHEL 7.x branch operating systems.
- ONTAP Mediator 1.6 adds support for Rocky Linux 8 and 9.

## == Resolved issues

| Date of change | Change ID | Description                                                                                                                                                                                                                                                                                                                                     |
|----------------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10 Jan 2023    | 6567145   | <p>The following changes were made:</p> <ul style="list-style-type: none"> <li>Added support for additional operating systems for ONTAP Mediator: RHEL 9.6, 8.7, 9.0, and 9.1.</li> <li>Added new SCST version 3.7.0 to unblock issues for newly supported operating systems.</li> <li>Added support for Rocky Linux: Rocky 8 and 9.</li> </ul> |
| 24 Jan 2023    | 6621319   | Allowed pre-installed SCST library for ONTAP Mediator installations.                                                                                                                                                                                                                                                                            |
| 27 Feb 2023    | 6623764   | Implemented changes to always load the scst_disk kernel module when the mediator-scst service restarts. These changes ensure the service will always be ready to create new iSCSI targets using the standard logic.                                                                                                                             |

|-------------|---------|---------------------------------------------------------------------------------------------------------------|
| 28 Feb 2023 | 6625194 | Added a new option to the ONTAP Mediator installer: --skip-yum-dependencies                                   |
| 24 Mar 2023 | 6652840 | Updated the ONTAP Mediator installer so that it is able to reinstall or repair the SCST installation.         |
| 27 Mar 2023 | 6655179 | Fixed a parsing issue that occurred when the support bundle collection with a complex password was triggered. |
| 28 Mar 2023 | 6656739 | Changed the SCST comparison logic so that it will install the right version when ONTAP Mediator is upgraded.  |

= Install or upgrade

= Prepare to install or upgrade the ONTAP Mediator service

:icons: font

:relative\_path: ./mediator/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

To install the ONTAP Mediator service, you must ensure all prerequisites are met, get the installation package and run the installer on the host. This procedure is used for an installation or an upgrade of an existing installation.

- Beginning with ONTAP 9.7, you can use any version of ONTAP Mediator to monitor a MetroCluster IP configuration.
- Beginning with ONTAP 9.8, you can use any version of ONTAP Mediator to monitor an SM-BC relationship.

### Before you begin

You must meet the following prerequisites.

| ONTAP Mediator version | Supported Linux versions                                                                                                                                        |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.6                    | <ul style="list-style-type: none"> <li>• Red Hat Enterprise Linux: 8.4, 8.5, 8.6, 8.7, 9.0, 9.1</li> <li>• Rocky Linux 8 and 9</li> </ul>                       |
| 1.5                    | <ul style="list-style-type: none"> <li>• Red Hat Enterprise Linux: 7.6, 7.7, 7.8, 7.9, 8.1, 8.2, 8.3, 8.4, 8.5</li> <li>• CentOS: 7.6, 7.7, 7.8, 7.9</li> </ul> |
| 1.4                    | <ul style="list-style-type: none"> <li>• Red Hat Enterprise Linux: 7.6, 7.7, 7.8, 7.9, 8.1, 8.2, 8.3, 8.4, 8.5</li> <li>• CentOS: 7.6, 7.7, 7.8, 7.9</li> </ul> |
| 1.3                    | <ul style="list-style-type: none"> <li>• Red Hat Enterprise Linux: 7.6, 7.7, 7.8, 7.9, 8.1, 8.2, 8.3</li> <li>• CentOS: 7.6, 7.7, 7.8, 7.9</li> </ul>           |

1.2

- Red Hat Enterprise Linux: 7.6, 7.7, 7.8, 8.1
- CentOS: 7.6, 7.7, 7.8

The kernel version must match the operating system version.

- 64-bit physical installation or virtual machine
- 8 GB RAM
- User: Root access

Any library packages except the kernel can safely be updated but might require a reboot to take affect within the ONTAP Mediator application. A service window is recommended when a reboot is required.

If you install the `yum-utils` package, you can use the `needs-restarting` command.

The kernel core can be updated if it is being updated to a version that is still supported by the ONTAP Mediator version matrix. A reboot will be mandatory, so a service window is required.

The SCST kernel module must be uninstalled prior to the reboot, then re-installed after the reboot.

Upgrading to a kernel beyond the supported OS release for the specific ONTAP Mediator release is not support. (This likely indicates that the tested SCST module won't compile).

= Upgrade the host operating system and then the ONTAP Mediator  
:icons: font  
:relative\_path: ./mediator/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

To upgrade the host OS for ONTAP Mediator to a later version, you must first uninstall ONTAP Mediator.

### Before you begin

The best practices for installing Red Hat Enterprise Linux or CentOS and the associated repositories on your system are listed below. Systems installed or configured differently might require additional steps.

- You must install Red Hat Enterprise Linux or CentOS according to Red Hat best practices. Due to end-of-life support for CentOS 8.x versions, compatible versions of CentOS 8.x are not recommended.
- While installing the ONTAP Mediator service on Red Hat Enterprise Linux or CentOS, the system must have access to the appropriate repository so that the installation program can access and install all the required software dependencies.
- For the yum installer to find dependent software in the Red Hat Enterprise Linux repositories, you must have registered the system during the Red Hat Enterprise Linux installation or afterwards by using a valid Red Hat subscription.

See the Red Hat documentation for information about the Red Hat Subscription Manager.

- The following ports must be unused and available for the Mediator:
  - 31784

- 3260
- If using a third-party firewall: refer to [Firewall requirements for ONTAP Mediator](#)
- If the Linux host is in a location without access to the internet, you must ensure that the required packages are available in a local repository.

If you are using Link Aggregation Control Protocol (LACP) in a Linux environment, you must correctly configure the kernel and make sure the `sysctl net.ipv4.conf.all.arp_ignore` is set to "2".

## What you'll need

The following packages are required by the ONTAP Mediator service:

| All RHEL/CentOS versions                                                                                                                                                                                                                                                                                                        | Additional packages for RHEL 8.x / Rocky Linux 8                                                                                                                                                                  | Additional packages for RHEL 9.x / Rocky Linux 9                                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>• openssl</li> <li>• openssl-devel</li> <li>• kernel-devel-\$ (uname -r)</li> <li>• gcc</li> <li>• make</li> <li>• libselinux-utils</li> <li>• patch</li> <li>• bzip2</li> <li>• perl-Data-Dumper</li> <li>• perl-ExtUtils-MakeMaker</li> <li>• efibootmgr</li> <li>• mokutil</li> </ul> | <ul style="list-style-type: none"> <li>• python3-pip</li> <li>• elfutils-libelf-devel</li> <li>• policycoreutils-python-utils</li> <li>• redhat-lsb-core</li> <li>• python39</li> <li>• python39-devel</li> </ul> | <ul style="list-style-type: none"> <li>• python3-pip</li> <li>• elfutils-libelf-devel</li> <li>• policycoreutils-python-utils</li> <li>• python3</li> <li>• python3-devel</li> </ul> |

The Mediator installation package is a self-extracting compressed tar file that includes:

- An RPM file containing all dependencies that cannot be obtained from the supported release's repository.
- An install script.

A valid SSL certification is recommended.

## About this task

When you upgrade the host OS for ONTAP Mediator to a later major version (for example, from 7.x to 8.x) using the `leapp-upgrade` tool, you must uninstall ONTAP Mediator because the tool tries to detect new versions of any RPMs that are installed in the repositories that are registered with the system.

Because an .rpm file was installed as part of the ONTAP Mediator installer, it is included in that search. However, because that .rpm file was unpacked as part of the installer and not downloaded from a registered repository, an upgrade cannot be found. In this case, the `leapp-upgrade` tool uninstalls the package.

In order to preserve the log files, which will be used to triage support cases, you should back up the files

prior to doing an OS upgrade and restore them after a reinstall of the ONTAP Mediator package. Because the ONTAP Mediator is being reinstalled, any ONTAP Clusters that are connected to it will need to be reconnected after the new installation.

The following steps should be performed in order. Immediately after you reinstall ONTAP Mediator, you should stop the `ontap_mediator` service, replace the log files, and restart the service. This will ensure logs will not be lost.

## Steps

1. Back up the log files.

```
[rootmediator-host ~]# tar -czf ontap_mediator_file_backup.tgz -C /opt/netapp/lib/ontap_mediator ./log
./ontap_mediator/server_config/ontap_mediator.user_config.yaml
[rootmediator-host ~]# tar -tf ontap_mediator_file_backup.tgz
./log/
./log/ontap_mediator.log
./log/scstadmin.log
./log/ontap_mediator_stdout.log
./log/ontap_mediator_requests.log
./log/install_20230419134611.log
./log/scst.log
./log/ontap_mediator_syslog.log
./ontap_mediator/server_config/ontap_mediator.user_config.yaml
[rootmediator-host ~]#
```

2. Perform upgrade with `leapp-upgrade` tool.

```
[rootmediator-host ~]# leapp preupgrade --target 8.4
..<snip upgrade checks>..
..<fix issues found>..
[rootmediator-host ~]# leapp upgrade --target 8.4
..<snip upgrade>..
[rootmediator-host ~]# cat /etc/os-release | head -2
NAME="Red Hat Enterprise Linux"
VERSION="8.4 (Ootpa)"
[rootmediator-host ~]#
```

3. Reinstall ONTAP Mediator.

Perform the rest of the steps immediately after reinstalling ONTAP Mediator to prevent a loss of log files.

```
[rootmediator-host ~]# ontap-mediator-1.6.0/ontap-mediator-1.6.0
ONTAP Mediator: Self Extracting Installer
..<snip installation>..
[rootmediator-host ~]#
```

4. Stop the `ontap_mediator` service.

```
[rootmediator-host ~]# systemctl stop ontap_mediator
[rootmediator-host ~]#
```

5. Replace the log files.

```
[rootmediator-host ~]# tar -xf ontap_mediator_log_backup.tgz -C
/opt/netapp/lib/ontap_mediator
[rootmediator-host ~]#
```

6. Start the `ontap_mediator` service.

```
[rootmediator-host ~]# systemctl start ontap_mediator
[rootmediator-host ~]#
```

7. Reconnect all ONTAP clusters to the upgraded ONTAP Mediator

```

```

You should enable access to repositories so ONTAP Mediator can access the required packages during the installation process

### Steps

1. Determine which repositories must be accessed, as shown in the following table:

| If your operating system is... | You must provide access to these repositories...                                                                           |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| RHEL 7.x                       | <ul style="list-style-type: none"><li>• rhel-7-server-optional-rpms</li></ul>                                              |
| RHEL 8.x                       | <ul style="list-style-type: none"><li>• rhel-8-for-x86_64-baseos-rpms</li><li>• rhel-8-for-x86_64-appstream-rpms</li></ul> |
| RHEL 9.x                       | <ul style="list-style-type: none"><li>• rhel-9-for-x86_64-baseos-rpms</li><li>• rhel-9-for-x86_64-appstream-rpms</li></ul> |
| CentOS 7.x                     | <ul style="list-style-type: none"><li>• C7.6.1810 - Base repository</li></ul>                                              |
| Rocky Linux 8                  | <ul style="list-style-type: none"><li>• appstream</li><li>• baseos</li></ul>                                               |
| Rocky Linux 9                  | <ul style="list-style-type: none"><li>• appstream</li><li>• baseos</li></ul>                                               |

2. Use one of the following procedures to enable access to the repositories listed above so ONTAP Mediator can access the required packages during the installation process.

Use this procedure if your operating system is **RHEL 7.x** to enable access to repositories:

### Steps

1. Subscribe to the required repository:

```
subscription-manager repos --enable rhel-7-server-optional-rpms
```

The following example shows the execution of this command:

```
[root@localhost ~]# subscription-manager repos --enable rhel-7-server-optional-rpms
Repository 'rhel-7-server-optional-rpms' is enabled for this system.
```

## 2. Run the `yum repolist` command.

The following example shows the execution of this command. The "rhel-7-server-optional-rpms" repository should appear in the list.

```
[root@localhost ~]# yum repolist
Loaded plugins: product-id, search-disabled-repos, subscription-manager
rhel-7-server-optional-rpms | 3.2 kB 00:00:00
rhel-7-server-rpms | 3.5 kB 00:00:00
(1/3): rhel-7-server-optional-rpms/7Server/x86_64/group |
26 kB 00:00:00
(2/3): rhel-7-server-optional-rpms/7Server/x86_64/updateinfo |
2.5 MB 00:00:00
(3/3): rhel-7-server-optional-rpms/7Server/x86_64/primary_db |
8.3 MB 00:00:01
repo id repo name
status
rhel-7-server-optional-rpms/7Server/x86_64 Red Hat Enterprise Linux 7
Server - Optional (RPMs) 19,447
rhel-7-server-rpms/7Server/x86_64 Red Hat Enterprise Linux 7
Server (RPMs) 26,758
repolist: 46,205
[root@localhost ~]#
```

Use this procedure if your operating system is **RHEL 8.x** to enable access to repositories:

### Steps

#### 1. Subscribe to the required repository:

```
subscription-manager repos --enable rhel-8-for-x86_64-baseos-rpms
subscription-manager repos --enable rhel-8-for-x86_64-appstream-rpms
```

The following example shows the execution of this command:

```
[root@localhost ~]# subscription-manager repos --enable rhel-8-for-
x86_64-baseos-rpms
Repository 'rhel-8-for-x86_64-baseos-rpms' is enabled for this system.
[root@localhost ~]# subscription-manager repos --enable rhel-8-for-
x86_64-appstream-rpms
Repository 'rhel-8-for-x86_64-appstream-rpms' is enabled for this
system.
```

## 2. Run the `yum repolist` command.

The newly subscribed repositories should appear in the list.

Use this procedure if your operating system is **RHEL 9.x** to enable access to repositories:

### Steps

1. Subscribe to the required repository:

```
subscription-manager repos --enable rhel-9-for-x86_64-baseos-rpms
```

```
subscription-manager repos --enable rhel-9-for-x86_64-appstream-rpms
```

The following example shows the execution of this command:

```
[root@localhost ~]# subscription-manager repos --enable rhel-9-for-x86_64-baseos-rpms
Repository 'rhel-9-for-x86_64-baseos-rpms' is enabled for this system.
[root@localhost ~]# subscription-manager repos --enable rhel-9-for-x86_64-appstream-rpms
Repository 'rhel-9-for-x86_64-appstream-rpms' is enabled for this system.
```

2. Run the `yum repolist` command.

The newly subscribed repositories should appear in the list.

Use this procedure if your operating system is **CentOS 7.x** to enable access to repositories:

The following examples are showing a repository for CentOS 7.6 and might not work for other CentOS versions. Use the base repository for your version of CentOS.

### Steps

1. Add the C7.6.1810 - Base repository. The C7.6.1810 - Base vault repository contains the "kernel-devel" package needed for ONTAP Mediator.
2. Add the following lines to `/etc/yum.repos.d/CentOS-Vault.repo`.

```
[C7.6.1810-base]
name=CentOS-7.6.1810 - Base
baseurl=http://vault.centos.org/7.6.1810/os/$basearch/
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-7
enabled=1
```

3. Run the `yum repolist` command.

The following example shows the execution of this command. The CentOS-7.6.1810 - Base repository should appear in the list.

```
Loaded plugins: fastestmirror
Loading mirror speeds from cached hostfile
 * base: distro.ibiblio.org
 * extras: distro.ibiblio.org
 * updates: ewr.edge.kernel.org
C7.6.1810-base | 3.6 kB 00:00:00
(1/2): C7.6.1810-base/x86_64/group_gz | 166 kB 00:00:00
(2/2): C7.6.1810-base/x86_64/primary_db | 6.0 MB 00:00:04
repo id repo name status
C7.6.1810-base/x86_64 CENTOS-7.6.1810 - Base 10,019
base/7/x86_64 CENTOS-7 - Base 10,097
extras/7/x86_64 CENTOS-7 - Extras 307
updates/7/x86_64 CENTOS-7 - Updates 1,010
repolist: 21,433
[root@localhost ~] #
```

Use this procedure if your operating system is **Rocky Linux 8** or **Rocky Linux 9** to enable access to repositories:

### Steps

1. Subscribe to the required repositories:

```
dnf config-manager --set-enabled baseos
dnf config-manager --set-enabled appstream
```

2. Perform a `clean` operation:

```
dnf clean all
```

3. Verify the list of repositories:

```
dnf repolist
```

### **Example for Rocky Linux 8**

```
[root@localhost ~]# dnf config-manager --set-enabled baseos
[root@localhost ~]# dnf config-manager --set-enabled appstream
[root@localhost ~]# dnf clean all
[root@localhost ~]# dnf repolist
repo id repo name
appstream Rocky Linux 8 - AppStream
baseos Rocky Linux 8 - BaseOS
[root@localhost ~]#
```

### **Example for Rocky Linux 9**

```
[root@localhost ~]# dnf config-manager --set-enabled baseos
[root@localhost ~]# dnf config-manager --set-enabled appstream
[root@localhost ~]# dnf clean all
[root@localhost ~]# dnf repolist
repo id repo name
appstream Rocky Linux 9 - AppStream
baseos Rocky Linux 9 - BaseOS
[root@localhost ~]#
```

= Download the Mediator installation package  
:icons: font  
:relative\_path: ./mediator/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

Download the Mediator installation package as part of the installation process.

## Steps

1. Download the Mediator installation package from the ONTAP Mediator page.

[ONTAP Mediator download page](#)

2. Confirm that the Mediator installation package is in the current working directory:

```
ls
```

```
[root@mediator-host ~]#ls
ontap-mediator-1.5.0.tgz
```

For ONTAP Mediator versions 1.4 and earlier, the installer is named `ontap-mediator`.

If you are at a location without access to the internet, you must ensure that the installer has access to the required packages.

3. If necessary, move the Mediator installation package from the download directory to the installation directory on the Linux Mediator host.
4. Unzip the installer package:

```
tar xvfz ontap-mediator-1.6.0.tgz
```

```
[root@scs000099753 ~]# tar xvfz ontap-mediator-1.6.0.tgz
ontap-mediator-1.6.0/
ontap-mediator-1.6.0/ONTAP-Mediator-production.pub
ontap-mediator-1.6.0/tsa-prod-chain-ONTAP-Mediator.pem
ontap-mediator-1.6.0/tsa-prod-ONTAP-Mediator.pem
ontap-mediator-1.6.0/csc-prod-ONTAP-Mediator.pem
ontap-mediator-1.6.0/csc-prod-chain-ONTAP-Mediator.pem
ontap-mediator-1.6.0/ontap-mediator-1.6.0
ontap-mediator-1.6.0/ontap-mediator-1.6.0.sig.tsr
ontap-mediator-1.6.0/ontap-mediator-1.6.0.tsr
ontap-mediator-1.6.0/ontap-mediator-1.6.0.sig
```

= Verify the ONTAP Mediator code signature  
:icons: font  
:relative\_path: ./mediator/

You should verify the ONTAP Mediator code signature before installing the Mediator installation package.

### Before you begin

Before verifying the Mediator code signature, your system must meet the following requirements.

- openssl versions 1.0.2 to 3.0 for basic verification
- openssl version 1.1.0 or later for Time Stamping Authority (TSA) operations
- Public internet access for OCSP verification

The following files are included in the download package:

| File                              | Description                                                                             |
|-----------------------------------|-----------------------------------------------------------------------------------------|
| ONTAP-Mediator-development.pub    | The public key used to verify the signature                                             |
| csc-prod-chain-ONTAP-Mediator.pem | The public certification CA chain of trust                                              |
| csc-prod-ONTAP-Mediator.pem       | The certificate used to generate the key                                                |
| ontap-mediator-1.6.0              | The product installation executable for version 1.6.0                                   |
| ontap-mediator-1.6.0.sig          | The SHA-256 hashed, then RSA-signed using the csc-prod key, signature for the installer |
| ontap-mediator-1.6.0.sig.tsr      | The revocation request for use by OCSCP for the installer's signature                   |
| tsa-prod-ONTAP-Mediator.pem       | The public certificate for the TSR                                                      |
| tsa-prod-chain-ONTAP-Mediator.pem | The public certificate CA Chain for the TSR                                             |

### Steps

1. Perform the revocation check on `csc-prod-ONTAP-Mediator.pem` by using Online Certificate Status Protocol (OCSP).
  - a. Find the OCSP URL used to register the certificate because developer certificates might not provide a uri.

```
openssl x509 -noout -ocsp_uri -in csc-prod-chain-ONTAP-Mediator.pem
```

- b. Generate an OCSP request for the certificate.

```
openssl ocsp -issuer csc-prod-chain-ONTAP-Mediator.pem -CAfile
csc-prod-chain-ONTAP-Mediator.pem -cert csc-prod-ONTAP-
Mediator.pem -reqout req.der
```

c. Connect to the OCSP Manager to send the OCSP request:

```
openssl ocsp -issuer csc-prod-chain-ONTAP-Mediator.pem -CAfile
csc-prod-chain-ONTAP-Mediator.pem -cert csc-prod-ONTAP-
Mediator.pem -url ${ocsp_uri} -resp_text -respout resp.der
```

2. Verify the trust chain of the CSC and expiration dates against the local host:

```
openssl verify
```

The `openssl` version from the PATH must have a valid `cert.pem` (not self-signed).

```
openssl verify -untrusted csc-prod-chain-ONTAP-Mediator.pem -CApath
${OPENSSLDIR} csc-prod-ONTAP-Mediator.pem # Failure action: The
Code-Signature-Check certificate has expired or is invalid. Download
a newer version of the ONTAP Mediator.
openssl verify -untrusted tsa-prod-chain-ONTAP-Mediator.pem -CApath
${OPENSSLDIR} tsa-prod-ONTAP-Mediator.pem # Failure action: The
Time-Stamp certificate has expired or is invalid. Download a newer
version of the ONTAP Mediator.
```

3. Verify the `ontap-mediator-1.5.0.sig.tsr` and `ontap-mediator-1.6.0.tsr` files using the associated certificates:

```
openssl ts -verify
```

.tsr files contain the time stamp response associated with the installer and the code signature. Processing confirms that the time stamp has a valid signature from TSA and that your input file has not changed.

The verification is performed locally on your machine. Independently, there is no need to access TSA servers.

```
openssl ts -verify -data ontap-mediator-1.6.0.sig -in ontap-
mediator-1.6.0.sig.tsr -CAfile tsa-prod-chain-ONTAP-Mediator.pem
-untrusted tsa-prod-ONTAP-Mediator.pem
openssl ts -verify -data ontap-mediator-1.6.0 -in ontap-mediator-
1.6.0.tsr -CAfile tsa-prod-chain-ONTAP-Mediator.pem -untrusted tsa-
prod-ONTAP-Mediator.pem
```

4. Verify signatures against the key:

```
openssl -dgst -verify
```

```
openssl dgst -sha256 -verify ONTAP-Mediator-production.pub
-signature ontap-mediator-1.6.0.sig ontap-mediator-1.6.0
```

```
[root@scspa2695423001 ontap-mediator-1.6.0]# pwd

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/
```

To install the ONTAP Mediator service, you must get the installation package and run the installer on the host.

#### About this task

- Beginning with ONTAP Mediator 1.4, the Secure Boot mechanism is enabled on UEFI systems. When Secure Boot is enabled, you must take additional steps to register the security key after installation:
  - Follow instructions in the README file to sign the SCST kernel module.:  
`/opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys/README.modul  
e-signing`
  - Locate the required keys:  
`/opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys`

After installation, the README files and key location are also provided in the system output.

#### Steps

- Run the installer and respond to the prompts as required:

```
./ontap-mediator-1.6.0/ontap-mediator-1.6.0 -y
```

```
[root@scs000099753 ~]# ./ontap-mediator-1.5.0/ontap-mediator-1.6.0
-y
```

The installation process proceeds to create the required accounts and install required packages. If you have a previous version of Mediator installed on the host, you will be prompted to confirm that you want to upgrade.

```
[root@scs000099753 ~]# ./ontap-mediator-1.6.0/ontap-mediator-1.6.0 -y
ONTAP Mediator: Self Extracting Installer
```

```
+ Extracting the ONTAP Mediator installation/upgrade archive
+ Performing the ONTAP Mediator run-time code signature check
 Using openssl from the path: /usr/bin/openssl configured for
 CApath:/etc/pki/tls
+ Unpacking the ONTAP Mediator installer
```

ONTAP Mediator requires two user accounts. One for the service (netapp), and one for use by ONTAP to the mediator API (mediatoradmin). Using default account names: netapp + mediatoradmin

Enter ONTAP Mediator user account (mediatoradmin) password:

Re-Enter ONTAP Mediator user account (mediatoradmin) password:

+ Checking if SELinux is in enforcing mode

+ Checking for default Linux firewall

success

success

success

## Preparing for installation of ONTAP Mediator packages.

+ Installing required packages.

Last metadata expiration check: 0:25:24 ago on Fri 21 Oct 2022 04:00:13 PM EDT.

Package openssl-1:1.1.1k-4.el8.x86\_64 is already installed.

Package gcc-8.4.1-1.el8.x86\_64 is already installed.

Package python36-3.6.8-2.module+el8.1.0+3334+5cb623d7.x86\_64 is already installed.

Package libselinux-utils-2.9-5.el8.x86\_64 is already installed.

Package perl-Data-Dumper-2.167-399.el8.x86\_64 is already installed.

Package efibootmgr-16-1.el8.x86\_64 is already installed.

Package mokutil-1:0.3.0-11.el8.x86\_64 is already installed.

Package python3-pip-9.0.3-19.el8.noarch is already installed.

Package policycoreutils-python-utils-2.9-14.el8.noarch is already

installed.

Complete!

OS package installations finished

+ Installing ONTAP Mediator. (Log: /tmp/ontap\_mediator.JixKGP/ontap-mediator-1.6.0/ontap-mediator-1.6.0/install\_20221021155929.log)

This step will take several minutes. Use the log file to view progress.

Sudoer config verified

ONTAP Mediator rsyslog and logging rotation enabled

+ Install successful. (Moving log to

/opt/netapp/lib/ontap\_mediator/log/install\_20221021155929.log)

+ WARNING: This system supports UEFI

Secure Boot (SB) is currently disabled on this system.

If SB is enabled in the future, SCST will not work unless the following action is taken:

Using the keys in

/opt/netapp/lib/ontap\_mediator/ontap\_mediator/SCST\_mod\_keys follow

instructions in

/opt/netapp/lib/ontap\_mediator/ontap\_mediator/SCST\_mod\_keys/README.module-signing

to sign the SCST kernel module. Note that reboot will be needed.

SCST will not start automatically when Secure Boot is enabled and not configured properly.

+ Note: ONTAP Mediator uses a kernel module compiled specifically for the current

OS. Using 'yum update' to upgrade the kernel might cause service interruption.

For more information, see /opt/netapp/lib/ontap\_mediator/README

[root@scs000099753 ~]# cat /etc/redhat-release

Red Hat Enterprise Linux release 8.5 (Ootpa)

[root@scs000099753 ~]#

= Verify the installation  
:icons: font  
:relative\_path: ./mediator/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/./media/

After the ONTAP Mediator has been installed, you should verify that the ONTAP Mediator services are running.

## Steps

1. View the status of the ONTAP Mediator services:

a. `systemctl status ontap_mediator`

```
[root@scspr1915530002 ~]# systemctl status ontap_mediator

ontap_mediator.service - ONTAP Mediator
Loaded: loaded (/etc/systemd/system/ontap_mediator.service;
enabled; vendor preset: disabled)
Active: active (running) since Mon 2022-04-18 10:41:49 EDT; 1
weeks 0 days ago
Process: 286710 ExecStop=/bin/kill -s INT $MAINPID (code=exited,
status=0/SUCCESS)
Main PID: 286712 (uwsgi)
Status: "uWSGI is ready"
Tasks: 3 (limit: 49473)
Memory: 139.2M
CGroup: /system.slice/ontap_mediator.service
 └─286712 /opt/netapp/lib/ontap_mediator/pyenv/bin/uwsgi
--ini /opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini
 ├─286716 /opt/netapp/lib/ontap_mediator/pyenv/bin/uwsgi
--ini /opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini
 └─286717 /opt/netapp/lib/ontap_mediator/pyenv/bin/uwsgi
--ini /opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini

[root@scspr1915530002 ~]#
```

b. `systemctl status mediator-scst`

```
[root@scspr1915530002 ~]# systemctl status mediator-scst
 Loaded: loaded (/etc/systemd/system/mediator-scst.service; enabled; vendor preset: disabled)
 Active: active (running) since Mon 2022-04-18 10:41:47 EDT; 1 weeks 0 days ago
 Process: 286595 ExecStart=/etc/init.d/scst start (code=exited, status=0/SUCCESS)
 Main PID: 286662 (iscsi-scstd)
 Tasks: 1 (limit: 49473)
 Memory: 1.2M
 CGroup: /system.slice/mediator-scst.service
 └─286662 /usr/local/sbin/iscsi-scstd

[root@scspr1915530002 ~]#
```

## 2. Confirm the ports that are used by the ONTAP Mediator service:

netstat

```
[root@scspr1905507001 ~]# netstat -anlt | grep -E '3260|31784'

 tcp 0 0 0.0.0.0:31784 0.0.0.0:* LISTEN
 tcp 0 0 0.0.0.0:3260 0.0.0.0:* LISTEN
 tcp6 0 0 :::3260 :::* LISTEN
```

= Post-installation configuration

:icons: font

:relative\_path: ./mediator/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

After the ONTAP Mediator service is installed and running, additional configuration tasks must be performed in the ONTAP storage system to use the Mediator features:

- To use the ONTAP Mediator service in a MetroCluster IP configuration, see [Configuring the ONTAP Mediator service from a MetroCluster IP configuration](#).
- To use SnapMirror Business Continuity, see [Install ONTAP Mediator Service and confirm the ONTAP cluster configuration](#).

== Configure ONTAP Mediator security policies

The ONTAP Mediator server supports several configurable security settings. The default values for all settings are provided in a `low_space_threshold_mib: 10` read-only file:

`/opt/netapp/lib/ontap_mediator/server_config/ontap_mediator.user_config.yaml`

All values that are placed in the `ontap_mediator.user_config.yaml` will override the default values and be maintained across all ONTAP Mediator upgrades.

After you modify `ontap_mediator.user_config.yaml`, restart the ONTAP Mediator service:

```
systemctl restart ontap_mediator
```

The following attributes can be configured:

NOTE: Other default values in the `ontap_mediator.config.yaml` should not be modified.

- **Settings used to install third-party SSL certificates as replacements for the default self-signed certificates**

```
cert_path:
 '/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator_server.crt'
key_path:
 '/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ontap_mediator_server.key'
ca_cert_path:
 '/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ca.crt'
ca_key_path:
 '/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ca.key'
ca_serial_path:
 '/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config/ca.srl'
cert_valid_days: '1095' # Used to set the expiration on client certs to 3 years
x509_passin_pwd: 'pass:ontap' # passphrase for the signed client cert
```

- **Settings that provide protections against brute-force password guessing attacks**

To enable the feature, set a value for the `window_seconds` and the `retry_limit`

Examples:

- Provide a 5-minute window for guesses, and then reset the count to zero failures:

```
authentication_lock_window_seconds: 300
```

- Lock the account if five failures occur within the window timeframe:

```
authentication_retry_limit: 5
```

- Reduce the impact of brute-force password guessing attacks by setting a delay that occurs prior to rejecting each attempt, which slows the attacks.

```
authentication_failure_delay_seconds: 5
```

```
authentication_failure_delay_seconds: 0 # seconds (float) to delay failed auth attempts prior to response, 0 = no delay authentication_lock_window_seconds: null # seconds (int) since the oldest failure before resetting the retry counter, null = no window authentication_retry_limit: null # number of retries to allow before locking API access, null = unlimited
```

- **Fields that control the password complexity rules of the ONTAP Mediator API user account**

```
password_min_length: 8

password_max_length: 64

password_uppercase_chars: 0 # min. uppercase characters

password_lowercase_chars: 1 # min. lowercase character

password_special_chars: 1 # min. non-letter, non-digit

password_nonletter_chars: 2 # min. non-letter characters (digits, specials, anything)
```

- **Setting that controls the required free space on the /opt/netapp/lib/ontap\_mediator disk.**

If the space is lower than the set threshold, the service will issue a warning event.

```
low_space_threshold_mib: 10
```

```
= Manage the ONTAP mediator service
:icons: font
:relative_path: ./mediator/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/
```

After you have installed ONTAP Mediator service, you may change the user name or password. You may also uninstall the ONTAP Mediator Service.

== Change the user name

#### About these tasks

These task is performed on the Linux host on which the ONTAP Mediator service is installed.

If you are unable to reach this command, you might need to run the command using the full path as shown in the following example:

```
/usr/local/bin/mediator_username
```

## Procedure

Change the username by choosing one of the following options:

- Run the command `mediator_change_user` and respond to the prompts as shown in the following example:

```
[root@mediator-host ~]# mediator_change_user
Modify the Mediator API username by entering the following values:
Mediator API User Name: mediatoradmin
Password:
New Mediator API User Name: mediator
The account username has been modified successfully.
[root@mediator-host ~]#
```

- Run the following command:

```
MEDIATOR_USERNAME=mediator MEDIATOR_PASSWORD=mediator2
MEDIATOR_NEW_USERNAME=mediatoradmin mediator_change_user
```

```
[root@mediator-host ~]# MEDIATOR_USERNAME= mediator
MEDIATOR_PASSWORD='mediator2' MEDIATOR_NEW_USERNAME= mediatoradmin
mediator_change_user
The account username has been modified successfully.
[root@mediator-host ~]#
```

== Change the password

## About this task

This task is performed on the Linux host on which the ONTAP Mediator service is installed.

If you are unable to reach this command, you might need to run the command using the full path as shown in the following example:

```
/usr/local/bin/mediator_change_password
```

## Procedure

Change the password by choosing one of the following options:

- Run the `mediator_change_password` command and respond to the prompts as shown in the following example:

```
[root@mediator-host ~]# mediator_change_password
Change the Mediator API password by entering the following values:
 Mediator API User Name: mediatoradmin
 Old Password:
 New Password:
 Confirm Password:
The password has been updated successfully.
[root@mediator-host ~]#
```

- Run the following command:

```
MEDIATOR_USERNAME= mediatoradmin MEDIATOR_PASSWORD=mediator1
MEDIATOR_NEW_PASSWORD=mediator2 mediator_change_password
```

The example shows the password is changed from "mediator1" to "mediator2".

```
[root@mediator-host ~]# MEDIATOR_USERNAME=mediatoradmin
MEDIATOR_PASSWORD=mediator1 MEDIATOR_NEW_PASSWORD=mediator2
mediator_change_password
The password has been updated successfully.
[root@mediator-host ~]#
```

## == Stop the ONTAP Mediator service

To stop the ONTAP Mediator service, perform the following steps:

### Steps

1. Stop the ONTAP Mediator.

```
systemctl stop ontap_mediator
```

2. Stop SCST.

```
systemctl stop mediator-s cst
```

3. Disable the ONTAP Mediator and SCST.

```
systemctl disable ontap_mediator mediator-s cst
```

## == Re-enable the ONTAP Mediator service

To re-enable the ONTAP Mediator service, perform the following steps:

### Steps

1. Enable the ONTAP Mediator and SCST.

```
systemctl enable ontap_mediator mediator-s cst
```

2. Start SCST.

```
systemctl start mediator-scst
```

### 3. Start ONTAP Mediator.

```
systemctl start ontap_mediator
```

== Verify the ONTAP Mediator is healthy

After the ONTAP Mediator has been installed, you should verify that the ONTAP Mediator services are running.

#### Steps

##### 1. View the status of the ONTAP Mediator services:

a. `systemctl status ontap_mediator`

```
[root@scspr1915530002 ~]# systemctl status ontap_mediator

ontap_mediator.service - ONTAP Mediator
Loaded: loaded (/etc/systemd/system/ontap_mediator.service; enabled;
 vendor preset: disabled)
Active: active (running) since Mon 2022-04-18 10:41:49 EDT; 1 weeks 0
 days ago
Process: 286710 ExecStop=/bin/kill -s INT $MAINPID (code=exited,
 status=0/SUCCESS)
Main PID: 286712 (uwsgi)
Status: "uWSGI is ready"
Tasks: 3 (limit: 49473)
Memory: 139.2M
CGroup: /system.slice/ontap_mediator.service
 └─286712 /opt/netapp/lib/ontap_mediator/pyenv/bin/uwsgi --ini
 /opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini
 ├─286716 /opt/netapp/lib/ontap_mediator/pyenv/bin/uwsgi --ini
 /opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini
 └─286717 /opt/netapp/lib/ontap_mediator/pyenv/bin/uwsgi --ini
 /opt/netapp/lib/ontap_mediator/uwsgi/ontap_mediator.ini

[root@scspr1915530002 ~]#
```

b. `systemctl status mediator-scst`

```
[root@scspr1915530002 ~]# systemctl status mediator-scst
 Loaded: loaded (/etc/systemd/system/mediator-scst.service;
 enabled; vendor preset: disabled)
 Active: active (running) since Mon 2022-04-18 10:41:47 EDT; 1
 weeks 0 days ago
 Process: 286595 ExecStart=/etc/init.d/scst start (code=exited,
 status=0/SUCCESS)
 Main PID: 286662 (iscsi-scstd)
 Tasks: 1 (limit: 49473)
 Memory: 1.2M
 CPU: 0.000 CPU(s) (idle)
 CGroup: /system.slice/mediator-scst.service
 └─286662 /usr/local/sbin/iscsi-scstd

[root@scspr1915530002 ~]#
```

## 2. Confirm the ports that are used by the ONTAP Mediator service:

netstat

```
[root@scspr1905507001 ~]# netstat -anlt | grep -E '3260|31784'

 tcp 0 0 0.0.0.0:31784 0.0.0.0:* LISTEN
 tcp 0 0 0.0.0.0:3260 0.0.0.0:* LISTEN
 tcp6 0 0 :::3260 :::* LISTEN
```

-- Manually uninstall SCST to perform host maintenance

To uninstall SCST, you need the SCST tar bundle that is used for the installed version of ONTAP Mediator.

### Steps

1. Download the appropriate SCST bundle (as shown in the following table) and untar it.

| For this version ... | Use this tar bundle... |
|----------------------|------------------------|
| ONTAP Mediator 1.0   | scst-3.3.0.tar.bz2     |
| ONTAP Mediator 1.1   | scst-3.4.0.tar.bz2     |
| ONTAP Mediator 1.2   | scst-3.4.0.tar.bz2     |
| ONTAP Mediator 1.3   | scst-3.5.0.tar.bz2     |
| ONTAP Mediator 1.4   | scst-3.6.0.tar.bz2     |

|                    |                    |
|--------------------|--------------------|
| ONTAP Mediator 1.5 | scst-3.6.0.tar.bz2 |
| ONTAP Mediator 1.6 | scst-3.7.0.tar.bz2 |

2. Issue the following commands in the "scst" directory:

- a. systemctl stop mediator-scst
- b. make scstadm\_uninstall
- c. make iscsi\_uninstall
- d. make usr\_uninstall
- e. make scst\_uninstall
- f. depmod

== Manually install SCST to perform host maintenance

To manually install SCST, you need the SCST tar bundle that is used for the installed version of ONTAP Mediator (see the [table above](#)).

1. Issue the following commands in the "scst" directory:

- a. make 2release
- b. make scst\_install
- c. make usr\_install
- d. make iscsi\_install
- e. make scstadm\_install
- f. depmod
- g. cp scst/src/certs/scst\_module\_key.der  
/opt/netapp/lib/ontap\_mediator/ontap\_mediator/SCST\_mod\_keys/.
- h. cp scst/src/certs/scst\_module\_key.der  
/opt/netapp/lib/ontap\_mediator/ontap\_mediator/SCST\_mod\_keys/.
- i. patch /etc/init.d/scst < /opt/netapp/lib/ontap\_mediator/systemd/scst.patch

2. (Optional) If Secure Boot is enabled, before you reboot, perform the following steps:

- a. Determine each file name for "scst\_vdisk", "scst", and "iscsi\_scst" modules.

```
[root@localhost ~]# modinfo -n scst_vdisk
[root@localhost ~]# modinfo -n scst
[root@localhost ~]# modinfo -n iscsit_scst_vdisk
```

- b. Determine the kernel release.

```
[root@localhost ~]# uname -r
```

- c. Sign each file with the kernel.

```
[root@localhost ~]# /usr/src/kernels/<KERNEL-RELEASE>/scripts/sign-
file \sha256 \
/opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys/scst_modu
le_key.priv \
/opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys/scst_modu
le_key.der \
module-filename
```

- d. Install correct key with the UEFI firmware.

Instructions for installing the UEFI key are located at:

```
/opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys/README.module-
signing
```

The generated UEFI key is located at:

```
/opt/netapp/lib/ontap_mediator/ontap_mediator/SCST_mod_keys/scst_module_key.
der
```

3. Perform a reboot.

```
reboot
```

== Uninstall the ONTAP Mediator service

#### Before you begin

If necessary, you can remove the ONTAP Mediator service. The Mediator must be disconnected from ONTAP before you remove the Mediator service.

#### About this task

This task is performed on the Linux host on which the ONTAP Mediator service is installed.

If you are unable to reach this command, you might need to run the command using the full path as shown in the following example:

```
/usr/local/bin/uninstall_ontap_mediator
```

#### Step

1. Uninstall the ONTAP Mediator service:

```
uninstall_ontap_mediator
```

```
[root@mediator-host ~]# uninstall_ontap_mediator

ONTAP Mediator: Self Extracting Uninstaller

+ Removing ONTAP Mediator. (Log:
/tmp/ontap_mediator.GmRGdA/uninstall_ontap_mediator/remove.log)
+ Remove successful.

[root@mediator-host ~]#
```

= Maintain OS host for ONTAP Mediator

:icons: font

:relative\_path: ./mediator/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

For optimal performance, you should maintain the host OS for ONTAP Mediator on a regular basis.

== Reboot the host

Reboot the host when the clusters are healthy. While the ONTAP Mediator is offline, the clusters are at risk of not being able to react properly to failures. A service window is recommended if a reboot is required.

ONTAP Mediator will automatically resume during a reboot and will re-enter the relationships that were previously configured with ONTAP clusters.

== Host package updates

Any library or yum packages (except the kernel) can be safely updated but might require a reboot to take effect. A service window is recommended if a reboot is required.

If you install the yum-utils package, use the needs-restarting command to detect if any package changes require a reboot.

You should reboot if any of the ONTAP Mediator dependencies are updated because they will not take immediate effect on running processes.

== Host OS minor kernel upgrades

SCST must be compiled for the kernel that is being used. To update the OS, a maintenance window is required.

## Steps

Perform the following steps to upgrade the host OS kernel.

1. Stop the ONTAP Mediator
2. Uninstall the SCST package. (SCST doesn't provide an upgrade mechanism.)
3. Upgrade the OS, and reboot.
4. Re-install the SCST package.
5. Re-enable the ONTAP Mediator services.

= Manage MetroCluster sites with System Manager

= MetroCluster site management overview with System Manager

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkattrs:

:relative\_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest./media/

Beginning with ONTAP 9.8, you can use System Manager as a simplified interface for managing a configuration of a MetroCluster setup.

A MetroCluster configuration allows two clusters to mirror data to each other so if one cluster goes down, the data isn't lost.

Typically, an organization sets up the clusters in two separate geographical locations. An administrator at each location sets up a cluster and configures it. Then one of the administrators can set up the peering between the clusters so that they can share data.

The organization can also install an ONTAP Mediator in a third location. The ONTAP Mediator service monitors the status of each cluster. When one of the clusters detects that it cannot communicate with the partner cluster, it queries the monitor to determine if the error is a problem with the cluster system or with the network connection.

If the problem is with the network connection, the system administrator performs troubleshooting methods to correct the error and reconnect. If the partner cluster is down, the other cluster initiates a switchover process to control the data I/O for both clusters.

You can also perform a switchover to bring down one of the cluster systems for planned maintenance. The partner cluster handles all data I/O operations for both clusters until you bring up the cluster on which you performed maintenance and perform a switchback operation.

You can manage the following operations:

- [Set up an IP MetroCluster site](#)
- [Set up IP MetroCluster peering](#)
- [Configure an IP MetroCluster site](#)
- [Perform IP MetroCluster switchover and switchback](#)
- [Troubleshoot problems with IP MetroCluster configurations](#)
- [Upgrade ONTAP on MetroCluster clusters](#)

= Set up an IP MetroCluster site

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkattrs:

:relative\_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest./media/

Beginning with ONTAP 9.8, you can use System Manager to set up an IP configuration of a MetroCluster site.

A MetroCluster site consists of two clusters. Typically, the clusters are located in different geographical locations.

### Before you start

- Your system should already be installed and cabled according to the [Installation and Setup Instructions](#) that came with the system.
- Cluster network interfaces should be configured on each node of each cluster for intra-cluster communication.

== Assign a node-management IP address

== Windows System

You should connect your Windows computer to the same subnet as the controllers. This will automatically assign a node-management IP address to your system.

### Steps

1. From the Windows system, open the **Network** drive to discover the nodes.
2. Double-click the node to launch the cluster setup wizard.

== Other systems

You should configure the node-management IP address for one of the nodes in your cluster. You can use this node-management IP address to launch the cluster set up wizard.

See [Creating the cluster on the first node](#) for information about assigning a node-management IP address.

== Initialize and configure the cluster

You initialize the cluster by setting an administrative password for the cluster and setting up the cluster management and node management networks. You can also configure services like a DNS server to resolve host names and an NTP server to synchronize time.

### Steps

1. On a web browser, enter the node-management IP address that you have configured: "<https://node-management-IP>"

System Manager automatically discovers the remaining nodes in the cluster.

2. In the **Initialize Storage System** window, perform the following:
  - a. Enter cluster management network configuration data.
  - b. Enter Node management IP addresses for all the nodes.
  - c. Provide domain name servers (DNS) details.
  - d. In the **Other** section, select the check box labeled **Use time service (NTP)** to add the time servers.

When you click **Submit**, wait for the cluster to be created and configured. Then, a validation process occurs.

### What's Next?

After both clusters have been set up, initialized, and configured, perform the following procedure:

- [Set up IP MetroCluster peering](#)

== Configure ONTAP on a new cluster video

= Set up IP MetroCluster peering

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkattrs:

:relative\_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.//encryption-at-rest//media/

Beginning with ONTAP 9.8, you can manage an IP configuration of a MetroCluster operation with System Manager. After setting up two clusters, you set up peering between them.

### Before you start

You should have completed the following procedure to set up two clusters:

- [Set up an IP MetroCluster site](#)

Certain steps of this process are performed by different system administrators located at the geographical sites of each cluster. For the purposes of explaining this process, the clusters are called "Site A cluster" and "Site B cluster".

== Performing the peering process from Site A

This process is performed by a system administrator at Site A.

### Steps

1. Log in to Site A cluster.

2. In System Manager, select **Dashboard** from the left navigation column to display the cluster overview.

The dashboard shows the details for this cluster (Site A). In the **MetroCluster** section, Site A cluster is shown on the left.

3. Click **Attach Partner Cluster**.

4. Enter the details of the network interfaces that allow the nodes in Site A cluster to communicate with the nodes in Site B cluster.

5. Click **Save and Continue**.

6. On the **Attach Partner Cluster** window, select **I do not have a passphrase**, which lets you generate a passphrase.

7. Copy the generated passphrase and share it with the system administrator at Site B.

8. Select **Close**.

== Performing the peering process from Site B

This process is performed by a system administrator at Site B.

## Steps

1. Log in to Site B cluster.

2. In System Manager, select **Dashboard** to display the cluster overview.

The dashboard shows the details for this cluster (Site B). In the MetroCluster section, Site B cluster is shown on the left.

3. Click **Attach Partner Cluster** to start the peering process.

4. Enter the details of the network interfaces that allow the nodes in Site B cluster to communicate with the nodes in Site A cluster.

5. Click **Save and Continue**.

6. On the **Attach Partner Cluster** window, select **I have a passphrase**, which lets you enter the passphrase that you received from the system administrator at Site A.

7. Select **Peer** to complete the peering process.

## What's next?

After the peering process is successfully completed, you configure the clusters. See [Configure an IP MetroCluster site](#).

= Configure an IP MetroCluster site

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkattrs:

:relative\_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest./media/

Beginning with ONTAP 9.8, you can manage an IP configuration of a MetroCluster operation with System Manager. After setting up two clusters and peering them, you configure each cluster.

## Before you start

You should have completed the following procedures:

- [Set up an IP MetroCluster site](#)
- [Set up IP MetroCluster peering](#)

== Configure the connection between clusters

### Steps

1. Log in to System Manager on one of the sites, and select **Dashboard**.

In the **MetroCluster** section, the graphic shows the two clusters that you set up and peered for the MetroCluster sites. The cluster you are working from (local cluster) is shown on the left.

2. Click **Configure MetroCluster**. From this window, you can perform the following tasks:

- The nodes for each cluster in the MetroCluster configuration are shown. Use the drop-down lists to select which nodes in the local cluster will be disaster recovery partners with which nodes in the remote cluster.
- Click the check box if you want to configure an ONTAP Mediator service. See [\[Configure the ONTAP Mediator service\]](#).
- If both clusters have a license to enable encryption, the **Encryption** section is displayed.  
To enable encryption, enter a passphrase.
- Click the check box if you want to configure MetroCluster with shared layer 3 network.

The HA partner nodes and network switches connecting to the nodes must have a matching configuration.

3. Click **Save** to configure the MetroCluster sites.

On the **Dashboard**, in the **MetroCluster** section, the graphic shows a check mark on the link between the two clusters, indicating a healthy connection.

== Configure the ONTAP Mediator service

The ONTAP Mediator service is typically installed at a geographic location separate from either location of the clusters. The clusters communicate regularly with the service to indicate that they are up and running. If one of the clusters in the MetroCluster configuration detects that the communication with its partner cluster is down, it checks with the ONTAP Mediator to determine if the partner cluster itself is down.

## Before you start

Both clusters at the MetroCluster sites should be up and peered.

### Steps

1. In System Manager in ONTAP 9.8, select **Cluster > Settings**.
2. In the **Mediator** section, click
3. On the **Configure Mediator** window, click **Add+**.
4. Enter the configuration details for the ONTAP Mediator.

```
= Perform IP MetroCluster switchover and switchback
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkattrs:
:relative_path: ../
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/../encryption-at-rest./media/
```

You can switch over control from one IP MetroCluster site to the other to perform maintenance or recover from an issue.

Switchover and switchback procedures are supported only for IP MetroCluster configurations.

## == Overview of switchover and switchback

A switchover can occur in two instances:

- **A planned switchover**

This switchover is initiated by a system administrator using System Manager. The planned switchover allows a system administrator of a local cluster to switch control so that the data services of the remote cluster are handled by the local cluster. Then, a system administrator at the remote cluster location can perform maintenance on the remote cluster.

- **An unplanned switchover**

In some cases, when a MetroCluster cluster goes down or the connections between the clusters are down, ONTAP will automatically initiate a switchover procedure so that the cluster that is still running handles the data handling responsibilities of the down cluster.

At other times, when ONTAP cannot determine the status of one of the clusters, the system administrator of the site that is working initiates the switchover procedure to take control of the data handling responsibilities of the other site.

For any type of switchover procedure, the data servicing capability is returned to the cluster by using a *switchback* process.

You perform different switchover and switchback processes for ONTAP 9.7 and 9.8:

- [Use System Manager in ONTAP 9.7 for switchover and switchback](#)
- [Use System Manager in ONTAP 9.8 for switchover and switchback](#)

## == Use System Manager in ONTAP 9.7 for switchover and switchback

### Steps

1. Log in to System Manager in ONTAP 9.7.
2. Click **(Return to classic version)**.
3. Click **Configuration > MetroCluster**.

System Manager verifies whether a negotiated switchover is possible.

4. Perform one of the following substeps when the validation process has completed:
  - a. If validation fails, but Site B is up, then an error has occurred. For example, there might be a problem with a subsystem, or NVRAM mirroring might not be synchronized.
    - i. Fix the issue that is causing the error, click **Close**, and then start again at Step 2.
    - ii. Halt the Site B nodes, click **Close**, and then perform the steps in [Performing an unplanned switchover](#).
  - b. If validation fails, and Site B is down, then most likely there is a connection problem. Verify that Site B is really down, then perform the steps in [Performing an unplanned switchover](#).
5. Click **Switchover from Site B to Site A** to initiate the switchover process.
6. Click **Switch to the new experience**.

== Use System Manager in ONTAP 9.8 for switchover and switchback

==== Perform a planned switchover (ONTAP 9.8)

### Steps

1. Log in to System Manager in ONTAP 9.8.
2. Select **Dashboard**. In the **MetroCluster** section, the two clusters are shown with a connection.
3. In the local cluster (shown on the left), click , and select **Switchover remote data services to the local site**.

After the switchover request is validated, control is transferred from the remote site to the local site, which performs data service requests for both clusters.

The remote cluster reboots, but the storage components are not active, and the cluster does not service data requests. It is now available for planned maintenance.

The remote cluster should not be used for data servicing until you perform a switchback.

==== Perform an unplanned switchover (ONTAP 9.8)

An unplanned switchover might be initiated automatically by ONTAP. If ONTAP cannot determine if a switchback is needed, the system administrator of the MetroCluster site that is still running initiates the switchover with the following steps:

### Steps

1. Log in to System Manager in ONTAP 9.8.
2. Select **Dashboard**.

In the **MetroCluster** section, the connection between the two clusters is shown with an "X" on it, meaning a connection cannot be detected. Either the connections or the cluster is down.

3. In the local cluster (shown on the left), click , and select **Switchover remote data services to the local site**.

If the switchover fails with an error, click on the "View details" link in the error message and confirm the unplanned switchover.

After the switchover request is validated, control is transferred from the remote site to the local site, which performs data service requests for both clusters.

The cluster must be repaired before it is brought online again.

After the remote cluster is brought online again, it should not be used for data servicing until you perform a switchback.

### ==== Perform a switchback (ONTAP 9.8)

#### Before you start

Whether the remote cluster was down due to planned maintenance or due to a disaster, it should now be up and running and waiting for the switchback.

#### Steps

1. On the local cluster, log in to System Manager in ONTAP 9.8.
2. Select **Dashboard**.

In the **MetroCluster** section, the two clusters are shown.

3. In the local cluster (shown on the left), click , and select **Take back control**.

The data is *healed* first, to ensure data is synchronized and mirrored between both clusters.

4. When the data healing is complete, click , and select **Initiate switchback**.

When the switchback is complete, both clusters are active and servicing data requests. Also, the data is being mirrored and synchronized between the clusters.

= Modify address, netmask, and gateway in a MetroCluster IP

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative\_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/../encryption-at-rest./media/

Beginning with ONTAP 9.10.1, you can change the following properties of a MetroCluster IP interface: IP address and mask, and gateway. You can use any combination of parameters to update.

You might need to update these properties, for example, if a duplicate IP address is detected or if a gateway needs to change in the case of a layer 3 network due to router configuration changes. You can only change one interface at a time. There will be traffic disruption on that interface until the other interfaces are updated and connections are reestablished.

You must make the changes on each port. Similarly, network switches also need to update their configuration. For example, if the gateway is updated, ideally it is changed on both nodes of an HA pair, since they are same. Plus the switch connected to those nodes also needs to update its gateway.

#### Step

Update the IP address, netmask, and gateway for each node and interface.

```
= Troubleshoot problems with IP MetroCluster configurations
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkattrs:
:relative_path: ../
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest./media/
```

Beginning with ONTAP 9.8, System Manager monitors the health of IP MetroCluster configurations and helps you identify and correct problems that might occur.

## == Overview of the MetroCluster Health Check

System Manager periodically checks the health of your IP MetroCluster configuration. When you view the MetroCluster section in the Dashboard, usually the message is "MetroCluster systems are healthy."

However, when a problem occurs, the message will show the number of events. You can click on that message and view the results of the health check for the following components:

- Node
- Network Interface
- Tier (Storage)
- Cluster
- Connection
- Volume
- Configuration Replication

The **Status** column identifies which components have problems, and the **Details** column suggests how to correct the problem.

## == MetroCluster troubleshooting

### Steps

1. In System Manager, select **Dashboard**.
2. In the **MetroCluster** section, notice the message.
  - a. If the message indicates that your MetroCluster configuration is healthy, and the connections between the clusters and the ONTAP Mediator are healthy (shown with check marks), then you have no problems to correct.
  - b. If the message lists the number of events, or the connections have gone down (shown with an "X"), then continue to the next step.
3. Click the message that shows the number of events.

The MetroCluster Health Report displays.

4. Troubleshoot the problems that appear in the report using the suggestions in the **Details** column.
5. When all the problems have been corrected, click **Check MetroCluster Health**.

The MetroCluster Health Check uses an intensive amount of resources, so it is recommended that you perform all your troubleshooting tasks before running the check.

The MetroCluster Health Check runs in the background. You can work on other tasks while you wait for it to finish.

= Data protection using tape backup

= Tape backup of FlexVol volumes overview

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

ONTAP supports tape backup and restore through Network Data Management Protocol (NDMP). NDMP allows you to back up data in storage systems directly to tape, resulting in efficient use of network bandwidth. ONTAP supports both dump and SMTape engines for tape backup.

You can perform a dump or SMTape backup or restore by using NDMP-compliant backup applications. Only NDMP version 4 is supported.

== Tape backup using dump

Dump is a Snapshot copy based backup in which your file system data is backed up to tape. The ONTAP dump engine backs up files, directories, and the applicable access control list (ACL) information to tape. You can back up an entire volume, an entire qtree, or a subtree that is not an entire volume or an entire qtree. Dump supports baseline, differential, and incremental backups.

== Tape backup using SMTape

SMTape is a Snapshot copy based disaster recovery solution from ONTAP that backs up blocks of data to tape. You can use SMTape to perform volume backups to tapes. However, you cannot perform a backup at the qtree or subtree level. SMTape supports baseline, differential, and incremental backups.

Beginning in ONTAP 9.13.1, Tape backup using SMTape is supporting with [SnapMirror Business Continuity](#).

= Tape backup and restore workflow

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You can perform tape backup and restore operations by using an NDMP-enabled backup application.

## About this task

The tape backup and restore workflow provides an overview of the tasks that are involved in performing tape backup and restore operations. For detailed information about performing a backup and restore operation, see the backup application documentation.

## Steps

1. Set up a tape library configuration by choosing an NDMP-supported tape topology.

## 2. Enable NDMP services on your storage system.

You can enable the NDMP services either at the node level or at the storage virtual machine (SVM) level. This depends on the NDMP mode in which you choose to perform the tape backup and restore operation.

## 3. Use NDMP options to manage NDMP on your storage system.

You can use NDMP options either at the node level or at the SVM level. This depends on the NDMP mode in which you choose to perform the tape backup and restore operation.

You can modify the NDMP options at the node level by using the `system services ndmp modify` command and at the SVM level by using the `vserver services ndmp modify` command. For more information about these commands, see the man pages.

## 4. Perform a tape backup or restore operation by using an NDMP-enabled backup application.

ONTAP supports both dump and SMTape engines for tape backup and restore.

For more information about using the backup application (also called *Data Management Applications* or *DMA*s) to perform backup or restore operations, see your backup application documentation.

= Use cases for choosing a tape backup engine

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

ONTAP supports two backup engines: SMTape and dump. You should be aware of the use cases for the SMTape and dump backup engines to help you choose the backup engine to perform tape backup and restore operations.

Dump can be used in the following cases:

- Direct Access Recovery (DAR) of files and directories
- Backup of a subset of subdirectories or files in a specific path
- Excluding specific files and directories during backups
- Preserving backup for long durations

SMTape can be used in the following cases:

- Disaster recovery solution
- Preserving deduplication savings and deduplication settings on the backed up data during a restore operation
- Backup of large volumes

= Manage tape drives

= Manage tape drives overview

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can verify tape library connections and view tape drive information before performing a tape backup or restore operation. You can use a nonqualified tape drive by emulating this to a qualified tape drive. You can also assign and remove tape aliases in addition to viewing existing aliases.

When you back up data to tape, the data is stored in tape files. File marks separate the tape files, and the files have no names. You specify a tape file by its position on the tape. You write a tape file by using a tape device. When you read the tape file, you must specify a device that has the same compression type that you used to write that tape file.

= Commands for managing tape drives, media changers, and tape drive operations

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

There are commands for viewing information about tape drives and media changers in a cluster, bringing a tape drive online and taking it offline, modifying the tape drive cartridge position, setting and clearing tape drive alias name, and resetting a tape drive. You can also view and reset tape drive statistics.

For more information about these commands, see the man pages.

= Use a nonqualified tape drive

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can use a nonqualified tape drive on a storage system if it can emulate a qualified tape drive. It is then treated like a qualified tape drive. To use a nonqualified tape drive, you must first determine whether it emulates any of the qualified tape drives.

### About this task

A nonqualified tape drive is one that is attached to the storage system, but not supported or recognized by ONTAP.

### Steps

1. View the nonqualified tape drives attached to a storage system by using the storage tape show-

`supported-status` command.

The following command displays tape drives attached to the storage system and the support and qualification status of each tape drive. The nonqualified tape drives are also listed.

`tape_drive_vendor_name` is a nonqualified tape drive attached to the storage system, but not supported by ONTAP.

| cluster1::> storage tape show-supported-status -node Node1 |           |                       |            |
|------------------------------------------------------------|-----------|-----------------------|------------|
| Node: Node1                                                |           | Is                    |            |
| Tape Drive                                                 | Supported | Support Status        |            |
| "tape_drive_vendor_name"                                   | false     | Nonqualified          | tape drive |
| Hewlett-Packard C1533A                                     | true      | Qualified             |            |
| Hewlett-Packard C1553A                                     | true      | Qualified             |            |
| Hewlett-Packard Ultrium 1                                  | true      | Qualified             |            |
| Sony SDX-300C                                              | true      | Qualified             |            |
| Sony SDX-500C                                              | true      | Qualified             |            |
| StorageTek T9840C                                          | true      | Dynamically Qualified |            |
| StorageTek T9840D                                          | true      | Dynamically Qualified |            |
| Tandberg LTO-2 HH                                          | true      | Dynamically Qualified |            |

## 2. Emulate the qualified tape drive.

[NetApp Downloads: Tape Device Configuration Files](#)

### Related information

= Assign tape aliases  
:icons: font  
:relative\_path: ./tape-backup/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

For easy device identification, you can assign tape aliases to a tape drive or medium changer. Aliases provide a correspondence between the logical names of backup devices and a name permanently assigned to the tape drive or medium changer.

### Steps

1. Assign an alias to a tape drive or medium changer by using the `storage tape alias set` command.

For more information about this command, see the man pages.

You can view the serial number (SN) information about the tape drives by using the `system node hardware tape drive show` command and about tape libraries by using the `system node hardware tape library show` commands.

The following command sets an alias name to a tape drive with serial number SN[123456]L4 attached to

the node, cluster1-01:

```
cluster-01::> storage tape alias set -node cluster-01 -name st3
-mapping SN[123456]L4
```

The following command sets an alias name to a media changer with serial number SN[65432] attached to the node, cluster1-01:

```
cluster-01::> storage tape alias set -node cluster-01 -name mcl
-mapping SN[65432]
```

## Related information

[What tape aliasing is](#)

[Removing tape aliases](#)

= Remove tape aliases

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

You can remove aliases by using the `storage tape alias clear` command when persistent aliases are no longer required for a tape drive or medium changer.

## Steps

1. Remove an alias from a tape drive or medium changer by using the `storage tape alias clear` command.

For more information about this command, see the man pages.

The following command removes the aliases of all tape drives by specifying the scope of the alias clear operation to tape:

```
cluster-01::>storage tape alias clear -node cluster-01 -clear-scope tape
```

## After you finish

If you are performing a tape backup or restore operation using NDMP, then after you remove an alias from a tape drive or medium changer, you must assign a new alias name to the tape drive or medium changer to continue access to the tape device.

## Related information

[What tape aliasing is](#)

= Enabling or disabling tape reservations

:icons: font

```
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/
```

You can control how ONTAP manages tape device reservations by using the `tape.reservations` option. By default, tape reservation is turned off.

### About this task

Enabling the tape reservations option can cause problems if tape drives, medium changers, bridges, or libraries do not work properly. If tape commands report that the device is reserved when no other storage systems are using the device, this option should be disabled.

### Steps

1. To use either the SCSI Reserve/Release mechanism or SCSI Persistent Reservationsor to disable tape reservations, enter the following commandat the clustershell:

```
options -option-name tape.reservations -option-value {scsi | persistent | off}
```

`scsi` selects the SCSI Reserve/Release mechanism.

`persistent` selects SCSI Persistent Reservations.

`off` disables tape reservations.

### Related information

#### [What tape reservations are](#)

= Commands for verifying tape library connections

:icons: font

```
:relative_path: ./tape-backup/
```

```
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/
```

You can view information about the connection path between a storage system and a tape library configuration attached to the storage system. You can use this information to verify the connection path to the tape library configuration or for troubleshooting issues related to the connection paths.

You can view the following tape library details to verify the tape library connections after adding or creating a new tape library, or after restoring a failed path in a single-path or multipath access to a tape library. You can also use this information while troubleshooting path-related errors or if access to a tape library fails.

- Node to which the tape library is attached
- Device ID
- NDMP path
- Tape library name
- Target port and initiator port IDs
- Single-path or multipath access to a tape library for every target or FC initiator port
- Path-related data integrity details, such as “Path Errors” and “Path Qual”
- LUN groups and LUN counts

= About tape drives

= Qualified tape drives overview

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You must use a qualified tape drive that has been tested and found to work properly on a storage system. You can follow tape aliasing and also enable tape reservations to ensure that only one storage system accesses a tape drive at any particular time.

A qualified tape drive is a tape drive that has been tested and found to work properly on storage systems. You can qualify tape drives for existing ONTAP releases by using the tape configuration file.

= Format of the tape configuration file

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

The tape configuration file format consists of fields such as vendor ID, product ID, and details of compression types for a tape drive. This file also consists of optional fields for enabling the autoload feature of a tape drive and changing the command timeout values of a tape drive.

The following table displays the format of the tape configuration file:

| Item               | Size           | Description                                             |
|--------------------|----------------|---------------------------------------------------------|
| vendor_id (string) | up to 8 bytes  | The vendor ID as reported by the SCSI Inquiry command.  |
| product_id(string) | up to 16 bytes | The product ID as reported by the SCSI Inquiry command. |

| Item                   | Size           | Description                                                                                                                                                                        |
|------------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| id_match_size(number)  |                | The number of bytes of the product ID to be used for matching to detect the tape drive to be identified, beginning with the first character of the product ID in the Inquiry data. |
| vendor.pretty (string) | up to 16 bytes | If this parameter is present, it is specified by the string displayed by the command, storage tape show -device-names; otherwise, INQ_VENDOR_ID is displayed.                      |
| product.pretty(string) | up to 16 bytes | If this parameter is present, it is specified by the string displayed by the command, storage tape show -device-names; otherwise, INQ_PRODUCT_ID is displayed.                     |

The vendor.pretty and product.pretty fields are optional, but if one of these fields has a value, the other must also have a value.

The following table explains the description, density code, and compression algorithm for the various compression types, such as l, m, h, and a:

| Item                                     | Size           | Description                                                                                                                                     |
|------------------------------------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| {l   m   h  <br>a}_description=(string)  | up to 24 bytes | The string to print for the nodeshell command, sysconfig -t, that describes characteristics of the particular density setting.                  |
| {l   m   h  <br>a}_density=(hex codes)   |                | The density code to be set in the SCSI mode page block descriptor corresponding to the desired density code for l, m, h, or a.                  |
| {l   m   h  <br>a}_algorithm=(hex codes) |                | The compression algorithm to be set in the SCSI Compression Mode Page corresponding to the density code and the desired density characteristic. |

The following table describes the optional fields available in the tape configuration file:

| Field                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| autoload=(Boolean yes/no) | This field is set to <code>yes</code> if the tape drive has an automatic loading feature; that is, after tape cartridge is inserted, the tape drive becomes ready without the need to execute a SCSI <code>load (start/stop unit)</code> command. The default for this field is <code>no</code> .                                                                                                                                                                              |
| cmd_timeout_0x            | <p>Individual timeout value. You must use this field only if you want to specify a different timeout value from the one being used as a default by the tape driver. The sample file lists the default SCSI command timeout values used by the tape drive. The timeout value can be expressed in minutes (m), seconds (s), or milliseconds (ms).</p> <p> You should not change this field.</p> |

You can download and view the tape configuration file from the NetApp Support Site.

#### Example of a tape configuration file format

The tape configuration file format for the HP LTO5 ULTRIUM tape drive is as follows:

```

vendor_id="HP"

product_id="Ultrium 5-SCSI"

id_match_size=9

vendor_pretty="Hewlett-Packard"

product_pretty="LTO-5"

l_description="LTO-3(ro)/4 4/800GB"

l_density=0x00

l_algorithm=0x00

m_description="LTO-3(ro)/4 8/1600GB cmp"

m_density=0x00

m_algorithm=0x01

h_description="LTO-5 1600GB"

h_density=0x58

h_algorithm=0x00

```

```
a_description="LTO-5 3200GB cmp"
```

```
a_density=0x58
```

```
a_algorithm=0x01
```

```
autoload="yes"
```

### [NetApp Tools: Tape Device Configuration Files](#)

= How the storage system qualifies a new tape drive dynamically

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

The storage system qualifies a tape drive dynamically by matching its vendor ID and product ID with the information contained in the tape qualification table.

When you connect a tape drive to the storage system, it looks for a vendor ID and product ID match between the information obtained during tape discovery and the information in the internal tape qualification table. If the storage system discovers a match, it marks the tape drive as qualified and can access the tape drive. If the storage system cannot find a match, the tape drive remains in the unqualified state and is not accessed.

= Tape devices overview

= Tape devices overview

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

A tape device is a representation of a tape drive. It is a specific combination of rewind type and compression capability of a tape drive.

A tape device is created for each combination of rewind type and compression capability. Therefore, a tape drive or tape library can have several tape devices associated with it. You must specify a tape device to move, write, or read tapes.

When you install a tape drive or tape library on a storage system, ONTAP creates tape devices associated with the tape drive or tape library.

ONTAP detects tape drives and tape libraries and assigns logical numbers and tape devices to them. ONTAP detects the Fibre Channel, SAS, and parallel SCSI tape drives and libraries when they are connected to the interface ports. ONTAP detects these drives when their interfaces are enabled.

= Tape device name format

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

Each tape device has an associated name that appears in a defined format. The format includes information about the type of device, rewind type, alias, and compression type.

The format of a tape device name is as follows:

```
rewind_type st alias_number compression_type
```

`rewind_type` is the rewind type.

The following list describes the various rewind type values:

- **r**

ONTAP rewinds the tape after it finishes writing the tape file.

- **nr**

ONTAP does not rewind the tape after it finishes writing the tape file. You must use this rewind type when you want to write multiple tape files on the same tape.

- **ur**

This is the unload/reload rewind type. When you use this rewind type, the tape library unloads the tape when it reaches the end of a tape file, and then loads the next tape, if there is one.

You must use this rewind type only under the following circumstances:

- The tape drive associated with this device is in a tape library or is in a medium changer that is in the library mode.
- The tape drive associated with this device is attached to a storage system.
- Sufficient tapes for the operation that you are performing are available in the library tape sequence defined for this tape drive.

If you record a tape using a no-rewind device, you must rewind the tape before you read it.

`st` is the standard designation for a tape drive.

`alias_number` is the alias that ONTAP assigns to the tape drive. When ONTAP detects a new tape drive, ONTAP assigns an alias to the tape drive.

`compression_type` is a drive-specific code for the density of data on the tape and the type of compression.

The following list describes the various values for `compression_type`:

- **a**

Highest compression

- **h**

High compression

- **m**

Medium compression

- |

Low compression

## Examples

nrst0a specifies a no-rewind device on tape drive 0 using the highest compression.

### Example of a listing of tape devices

The following example shows the tape devices associated with HP Ultrium 2-SCSI:

```
Tape drive (fc202_6:2.126L1) HP Ultrium 2-SCSI
rst01 - rewind device, format is: HP (200GB)
nrst01 - no rewind device, format is: HP (200GB)
urst01 - unload/reload device, format is: HP (200GB)
rst0m - rewind device, format is: HP (200GB)
nrst0m - no rewind device, format is: HP (200GB)
urst0m - unload/reload device, format is: HP (200GB)
rst0h - rewind device, format is: HP (200GB)
nrst0h - no rewind device, format is: HP (200GB)
urst0h - unload/reload device, format is: HP (200GB)
rst0a - rewind device, format is: HP (400GB w/comp)
nrst0a - no rewind device, format is: HP (400GB w/comp)
urst0a - unload/reload device, format is: HP (400GB w/comp)
```

The following list describes the abbreviations in the preceding example:

- GB—Gigabytes; this is the capacity of the tape.
- w/comp—With compression; this shows the tape capacity with compression.

= Supported number of simultaneous tape devices

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

ONTAP supports a maximum of 64 simultaneous tape drive connections, 16 medium changers, and 16 bridge or router devices for each storage system (per node) in any mix of Fibre Channel, SCSI, or SAS attachments.

Tape drives or medium changers can be devices in physical or virtual tape libraries or stand-alone devices.

Although a storage system can detect 64 tape drive connections, the maximum number of backup and restore sessions that can be performed simultaneously depends upon the scalability limits of the backup engine.

## Related information

[Scalability limits for dump backup and restore sessions](#)

= Tape aliasing

= Tape aliasing overview

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

Aliasing simplifies the process of device identification. Aliasing binds a physical path name (PPN) or a serial number (SN) of a tape or a medium changer to a persistent, but modifiable alias name.

The following table describes how tape aliasing enables you to ensure that a tape drive (or tape library or medium changer) is always associated with a single alias name:

| Scenario                                                | Reassigning of the alias                                       |
|---------------------------------------------------------|----------------------------------------------------------------|
| When the system reboots                                 | The tape drive is automatically reassigned its previous alias. |
| When a tape device moves to another port                | The alias can be adjusted to point to the new address.         |
| When more than one system uses a particular tape device | The user can set the alias to be the same for all the systems. |

When you upgrade from Data ONTAP 8.1.x to Data ONTAP 8.2.x, the tape alias feature of Data ONTAP 8.2.x modifies the existing tape alias names. In such a case you might have to update the tape alias names in the backup application.

Assigning tape aliases provides a correspondence between the logical names of backup devices (for example, st0 or mc1) and a name permanently assigned to a port, a tape drive, or a medium changer.

st0 and st00 are different logical names.

Logical names and serial numbers are used only to access a device. After the device is accessed, it returns all error messages by using the physical path name.

There are two types of names available for aliasing: physical path name and serial number.

= What physical path names are

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

Physical path names (PPNs) are the numerical address sequences that ONTAP assigns to tape drives and tape libraries based on the SCSI-2/3 adapter or switch (specific location) they are connected to the storage system. PPNs are also known as electrical names.

PPNs of direct-attached devices use the following format: host\_adapter.device\_id\_lun

The LUN value is displayed only for tape and medium changer devices whose LUN values are not zero; that is, if the LUN value is zero the lun part of the PPN is not displayed.

For example, the PPN 8.6 indicates that the host adapter number is 8, the device ID is 6, and the logical unit number (LUN) is 0.

SAS tape devices are also direct-attached devices. For example, the PPN 5c.4 indicates that in a storage system, the SAS HBA is connected in slot 5, SAS tape is connected to port C of the SAS HBA, and the device ID is 4.

PPNs of Fibre Channel switch-attached devices use the following format: `switch:port_id.device_id_lun`

For example, the PPN `MY_SWITCH:5.3L2` indicates that the tape drive connected to port 5 of a switch called `MY_SWITCH` is set with device ID 3 and has the LUN 2.

The LUN (logical unit number) is determined by the drive. Fibre Channel, SCSI tape drives and libraries, and disks have PPNs.

PPNs of tape drives and libraries do not change unless the name of the switch changes, the tape drive or library moves, or the tape drive or library is reconfigured. PPNs remain unchanged after reboot. For example, if a tape drive named `MY_SWITCH:5.3L2` is removed and a new tape drive with the same device ID and LUN is connected to port 5 of the switch `MY_SWITCH`, the new tape drive would be accessible by using `MY_SWITCH:5.3L2`.

= What serial numbers are

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

A serial number (SN) is a unique identifier for a tape drive or a medium changer. ONTAP generates aliases based on SN instead of the WWN.

Since the SN is a unique identifier for a tape drive or a medium changer, the alias remains the same regardless of the multiple connection paths to the tape drive or medium changer. This helps storage systems to track the same tape drive or medium changer in a tape library configuration.

The SN of a tape drive or a medium changer does not change even if you rename the Fibre Channel switch to which the tape drive or medium changer is connected. However, in a tape library if you replace an existing tape drive with a new one, then ONTAP generates new aliases because the SN of the tape drive changes. Also, if you move an existing tape drive to a new slot in a tape library or remap the tape drive's LUN, ONTAP generates a new alias for that tape drive.

You must update the backup applications with the newly generated aliases.

The SN of a tape device uses the following format: `SN [xxxxxxxxxx] L [X]`

`x` is an alphanumeric character and `Lx` is the LUN of the tape device. If the LUN is 0, the `Lx` part of the string is not displayed.

Each SN consists of up to 32 characters; the format for the SN is not case-sensitive.

= Considerations when configuring multipath tape access

```
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/
```

You can configure two paths from the storage system to access the tape drives in a tape library. If one path fails, the storage system can use the other paths to access the tape drives without having to immediately repair the failed path. This ensures that tape operations can be restarted.

You must consider the following when configuring multipath tape access from your storage system:

- In tape libraries that support LUN mapping, for multipath access to a LUN group, LUN mapping must be symmetrical on each path.

Tape drives and media changers are assigned to LUN groups (set of LUNs that share the same initiator path set) in a tape library. All tape drives of a LUN group must be available for backup and restore operations on all multiple paths.

- A maximum of two paths can be configured from the storage system to access the tape drives in a tape library.
- Multipath tape access supports load balancing. Load balancing is disabled by default.

In the following example, the storage system accesses LUN group 0 through two initiator paths: 0b and 0d. In both these paths, the LUN group has the same LUN number, 0, and LUN count, 5. The storage system accesses LUN group 1 through only one initiator path, 3d.

```
STSW-3070-2_cluster::> storage tape library config show

Node LUN Group LUN Count Library Name Library
Target Port Initiator
----- ----- ----- -----
----- -----
STSW-3070-2_cluster-01 0 5 IBM 3573-TL_1
510a09800000412d 0b
0d
 1 2 IBM 3573-TL_2
50050763124b4d6f 3d

3 entries were displayed
```

For more information, see the man pages.

= How you add tape drives and libraries to storage systems

```
:icons: font
```

```
:relative_path: ./tape-backup/
```

```
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/
```

You can add tape drives and libraries to storage system dynamically (without taking the

storage system offline).

When you add a new medium changer, the storage system detects its presence and adds it to the configuration. If the medium changer is already referenced in the alias information, no new logical names are created. If the library is not referenced, the storage system creates a new alias for the medium changer.

In a tape library configuration, you must configure a tape drive or medium changer on LUN 0 of a target port for ONTAP to discover all medium changers and tape drives on that target port.

= What tape reservations are

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

Multiple storage systems can share access to tape drives, medium changers, bridges, or tape libraries. Tape reservations ensure that only one storage system accesses a device at any particular time by enabling either the SCSI Reserve/Release mechanism or SCSI Persistent Reservations for all tape drives, medium changers, bridges, and tape libraries.

All the systems that share devices in a library, whether switches are involved or not, must use the same reservation method.

The SCSI Reserve/Release mechanism for reserving devices works well under normal conditions. However, during interface error recovery procedures, reservations can be lost. If this occurs, initiators other than the reserved owner can access the device.

Reservations made with SCSI Persistent Reservations are not affected by error recovery mechanisms, such as loop reset or target reset; however, not all devices implement SCSI Persistent Reservations correctly.

= Transfer data using ndmpcopy

= Transfer data using ndmpcopy overview

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

The `ndmpcopy nodeshell` command transfers data between storage systems that support NDMP v4. You can perform both full and incremental data transfers. You can transfer full or partial volumes, qtrees, directories, or individual files.

#### About this task

Using ONTAP 8.x and earlier releases, incremental transfers are limited to a maximum of two levels (one full and up to two incremental backups).

Beginning with ONTAP 9.0 and later releases, incremental transfers are limited to a maximum of nine levels (one full and up to nine incremental backups).

You can run `ndmpcopy` at the nodeshell command line of the source and destination storage systems, or a storage system that is neither the source nor the destination of the data transfer. You can also run `ndmpcopy` on a single storage system that is both the source and the destination of the data transfer.

You can use IPv4 or IPv6 addresses of the source and destination storage systems in the `ndmpcopy`

command. The path format is /vserver\_name/volume\_name \[path\].

## Steps

1. Enable NDMP service on the source and destination storage systems:

| If you are performing data transfer at the source or destination in... | Use the following command...                                                                                                                                                                                                                                                                                                               |
|------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SVM-scoped NDMP mode                                                   | <code>vserver services ndmp on</code><br><br> For NDMP authentication in the admin SVM, the user account is admin and the user role is admin or backup. In the data SVM, the user account is vsadmin and the user role is vsadmin or vsadmin-backup role. |
| Node-scoped NDMP mode                                                  | <code>system services ndmp on</code>                                                                                                                                                                                                                                                                                                       |

2. Transfer data within a storage system or between storage systems using the `ndmpcopy` command at the nodeshell:

```
::> system node run -node <node_name> < ndmpcopy [options]
source_IP:source_path destination_IP:destination_path [-mcs {inet|inet6}] [-mcd {inet|inet6}] [-md {inet|inet6}]
```

DNS names are not supported in `ndmpcopy`. You must provide the IP address of the source and the destination. The loopback address (127.0.0.1) is not supported for the source IP address or the destination IP address.

- The `ndmpcopy` command determines the address mode for control connections as follows:
  - The address mode for control connection corresponds to the IP address provided.
  - You can override these rules by using the `-mcs` and `-mcd` options.
- If the source or the destination is the ONTAP system, then depending on the NDMP mode (node-scoped or SVM-scoped), use an IP address that allows access to the target volume.
- `source_path` and `destination_path` are the absolute path names till the granular level of volume, qtree, directory or file.
- `-mcs` specifies the preferred addressing mode for the control connection to the source storage system.

`inet` indicates an IPv4 address mode and `inet6` indicates an IPv6 address mode.

- `-mcd` specifies the preferred addressing mode for the control connection to the destination storage system.

`inet` indicates an IPv4 address mode and `inet6` indicates an IPv6 address mode.

- `-md` specifies the preferred addressing mode for data transfers between the source and the destination

storage systems.

`inet` indicates an IPv4 address mode and `inet6` indicates an IPv6 address mode.

If you do not use the `-md` option in the `ndmpcopy` command, the addressing mode for the data connection is determined as follows:

- If either of the addresses specified for the control connections is an IPv6 address, the address mode for the data connection is IPv6.
- If both the addresses specified for the control connections are IPv4 addresses, the `ndmpcopy` command first attempts an IPv6 address mode for the data connection.

If that fails, the command uses an IPv4 address mode.

An IPv6 address, if specified, must be enclosed within square brackets.

This sample command migrates data from a source path (`source_path`) to a destination path (`destination_path`).

```
> ndmpcopy -sa admin:<ndmp_password> -da admin:<ndmp_password>
 -st md5 -dt md5 192.0.2.129:<src_svm>/<src_vol>
 192.0.2.131:<dst_svm>/<dst_vol>
```

This sample command explicitly sets the control connections and the data connection to use IPv6 address mode:

```
> ndmpcopy -sa admin:<ndmp_password> -da admin:<ndmp_password> -st
 md5 -dt md5 -mcs inet6 -mcd inet6 -md
 inet6 [2001:0db8:1:1:209:6bff:feae:6d67]:<src_svm>/<src_vol>
 [2001:0ec9:1:1:200:7cgg:gfdf:7e78]:<dst_svm>/<dst_vol>
```

= Options for the `ndmpcopy` command

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You should understand the options available for the `ndmpcopy nodeshell` command to successfully transfer data.

The following table lists the available options. For more information, see the `ndmpcopy` man pages available through the nodeshell.

| Option                  | Description                                                                                                                                                                                                                                                                                                                                           |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -sa username:[password] | <p>This option sets the source authentication user name and password for connecting to the source storage system. This is a mandatory option.</p> <p>For a user without admin privilege, you must specify the user's system-generated NDMP-specific password. The system-generated password is mandatory for both admin and non-admin users.</p>      |
| -da username:[password] | <p>This option sets the destination authentication user name and password for connecting to the destination storage system. This is a mandatory option.</p>                                                                                                                                                                                           |
| -st {md5 text}          | <p>This option sets the source authentication type to be used when connecting to the source storage system. = NDMP for FlexVol volumes

= About NDMP for FlexVol volumes

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

The Network Data Management Protocol (NDMP) is a standardized protocol for controlling backup, recovery, and other types of data transfer between primary and secondary storage devices, such as storage systems and tape libraries.

By enabling NDMP support on a storage system, you enable that storage system to communicate with NDMP-enabled network-attached backup applications (also called *Data Management Applications* or *DMA*s), data servers, and tape servers participating in backup or recovery operations. All network communications occur over TCPIP or TCP/IPv6 network. NDMP also provides low-level control of tape drives and medium changers.

You can perform tape backup and restore operations in either node-scoped NDMP mode or storage virtual machine (SVM) scoped NDMP mode.

You must be aware of the considerations that you have to take into account while using NDMP, list of environment variables, and supported NDMP tape backup topologies. You can also enable or disable the enhanced DAR functionality. The two authentication methods supported by ONTAP for authenticating NDMP access to a storage system are: plaintext and challenge.

= About NDMP modes of operation

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can choose to perform tape backup and restore operations either at the node level as you have been doing until now or at the storage virtual machine (SVM) level. To perform these operations successfully at the SVM level, NDMP service must be enabled on the SVM.

If you upgrade from Data ONTAP 8.2 to Data ONTAP 8.3, the NDMP mode of operation used in 8.2 will continue to be retained post the upgrade from 8.2 to 8.3.

If you install a new cluster with Data ONTAP 8.2 or later, NDMP is in the SVM-scoped NDMP mode by default. To perform tape backup and restore operations in the node-scoped NDMP mode, you must explicitly enable the node-scoped NDMP mode.

= What node-scoped NDMP mode is

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

In the node-scoped NDMP mode, you can perform tape backup and restore operations at the node level. The NDMP mode of operation used in Data ONTAP 8.2 will continue to be retained post the upgrade from 8.2 to 8.3.

In the node-scoped NDMP mode, you can perform tape backup and restore operations on a node that owns the volume. To perform these operations, you must establish NDMP control connections on a LIF hosted on the node that owns the volume or tape devices.

This mode is deprecated and will be removed in a future major release.

= What SVM-scoped NDMP mode is

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can perform tape backup and restore operations at the storage virtual machine (SVM) level successfully if the NDMP service is enabled on the SVM. You can back up and restore all volumes hosted across different nodes in the SVM of a cluster if the backup application supports the CAB extension.

An NDMP control connection can be established on different LIF types. In the SVM-scoped NDMP mode, these LIFs belong to either the data SVM or admin SVM. The connection can be established on a LIF only if the NDMP service is enabled on the SVM that owns this LIF.

A data LIF belongs to the data SVM and the intercluster LIF, node-management LIF, and cluster-management LIF belong to the admin SVM.

In the SVM-scoped NDMP mode, the availability of volumes and tape devices for backup and restore operations depends on the LIF type on which the NDMP control connection is established and the status of the CAB extension. If your backup application supports the CAB extension and a volume and the tape device share the same affinity, then the backup application can perform a local backup or restore operation, instead of a three-way backup or restore operation.

= Considerations when using NDMP

:icons: font

```
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/
```

You must take into account a number of considerations when starting the NDMP service on your storage system.

- Each node supports a maximum of 16 concurrent backups, restores, or combination of the two using connected tape drives.
- NDMP services can generate file history data at the request of NDMP backup applications.

File history is used by backup applications to enable optimized recovery of selected subsets of data from a backup image. File history generation and processing might be time-consuming and CPU-intensive for both the storage system and the backup application.

SMTape does not support file history.

If your data protection is configured for disaster recovery—where the entire backup image will be recovered—you can disable file history generation to reduce backup time. See your backup application documentation to determine whether it is possible to disable NDMP file history generation.

- Firewall policy for NDMP is enabled by default on all LIF types.
- In node-scoped NDMP mode, backing up a FlexVol volume requires that you use the backup application to initiate a backup on a node that owns the volume.

However, you cannot back up a node root volume.

- You can perform NDMP backup from any LIF as permitted by the firewall policies.

If you use a data LIF, you must select a LIF that is not configured for failover. If a data LIF fails over during an NDMP operation, the NDMP operation fails and must be run again.

- In node-scoped NDMP mode and storage virtual machine (SVM) scoped NDMP mode with no CAB extension support, the NDMP data connection uses the same LIF as the NDMP control connection.
- During LIF migration, ongoing backup and restore operations are disrupted.

You must initiate the backup and restore operations after the LIF migration.

- The NDMP backup path is of the format `/vserver_name/volume_name/path_name`.

`path_name` is optional, and specifies the path of the directory, file, or Snapshot copy.

- When a SnapMirror destination is backed up to tape by using the dump engine, only the data in the volume is backed up.

However, if a SnapMirror destination is backed up to tape using SMTape, then the metadata is also backed up. The SnapMirror relationships and the associated metadata are not backed up to tape. Therefore, during restore, only the data on that volume is restored, but the associated SnapMirror relationships are not restored.

### System administration

= Environment variable

= Environment variables overview

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

Environment variables are used to communicate information about a backup or restore operation between an NDMP-enabled backup application and a storage system.

For example, if a user specifies that a backup application should back up /vserver1/vol1/dir1, the backup application sets the FILESYSTEM environment variable to /vserver1/vol1/dir1. Similarly, if a user specifies that a backup should be a level 1 backup, the backup application sets the LEVEL environment variable to 1 (one).

The setting and examining of environment variables are typically transparent to backup administrators; that is, the backup application sets them automatically.

A backup administrator rarely specifies environment variables; however, you might want to change the value of an environment variable from that set by the backup application to characterize or work around a functional or performance problem. For example, an administrator might want to temporarily disable file history generation to determine if the backup application's processing of file history information is contributing to performance issues or functional problems.

Many backup applications provide a means to override or modify environment variables or to specify additional environment variables. For information, see your backup application documentation.

= Environment variables supported by ONTAP

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

Environment variables are used to communicate information about a backup or restore operation between an NDMP-enabled backup application and a storage system. ONTAP supports environment variables, which have an associated default value. However, you can manually modify these default values.

If you manually modify the values set by the backup application, the application might behave unpredictably. This is because the backup or restore operations might not be doing what the backup application expected them to do. But in some cases, judicious modification might help in identifying or working around problems.

The following tables list the environment variables whose behavior is common to dump and SMTape and those variables that are supported only for dump and SMTape. These tables also contain descriptions of how the environment variables that are supported by ONTAP work if they are used:

In most cases, variables that have the value, Y also accept T and N also accept F.

== Environment variables supported for dump and SMTape

| Environment variable | Valid values   | Default | Description                                                                                                                                                                                                                                                                                                                                                  |
|----------------------|----------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DEBUG                | Y or N         | N       | Specifies that debugging information is printed.                                                                                                                                                                                                                                                                                                             |
| FILESYSTEM           | string         | none    | Specifies the path name of the root of the data that is being backed up.                                                                                                                                                                                                                                                                                     |
| NDMP_VERSION         | return_only    | none    | <p>You should not modify the NDMP_VERSION variable. Created by the backup operation, the NDMP_VERSION variable returns the NDMP version.</p> <p>ONTAP sets the NDMP_VERSION variable during a backup for internal use and to pass to a backup application for informational purposes. The NDMP version of an NDMP session is not set with this variable.</p> |
| PATHNAME_SEPARATOR   | return_value   | none    | <p>Specifies the path name separator character.</p> <p>This character depends on the file system being backed up. For ONTAP, the character "/" is assigned to this variable. The NDMP server sets this variable before starting a tape backup operation.</p>                                                                                                 |
| TYPE                 | dump or smtape | dump    | Specifies the type of backup supported to perform tape backup and restore operations.                                                                                                                                                                                                                                                                        |
| VERBOSE              | Y or N         | N       | Increases the log messages while performing a tape backup or restore operation.                                                                                                                                                                                                                                                                              |

== Environment variables supported for dump

| IGNORE_CTIME         | Y or N       | N       | <p>Specifies that a file is not incrementally backed up if only its ctime value has changed since the previous incremental backup.</p> <p>Some applications, such as virus scanning software, change the ctime value of a file within the inode, even though the file or its attributes have not changed. As a result, an incremental backup might back up files that have not changed. The IGNORE_CTIME variable should be specified only if incremental backups are taking an unacceptable amount of time or space because the ctime value was modified.</p> <p>The NDMP dump command sets IGNORE_CTIME to false by default. Setting it to true can result in the following data loss:</p> <ul style="list-style-type: none"> <li>1. If IGNORE_CTIME is set to true with a volume level incremental ndmpcopy, it results in the 2773 deleting</li> </ul> |

| Environment variable | Valid values | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|--------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IGNORE_QTREES        | Y or N       | N       | Specifies that the restore operation does not restore qtree information from backed-up qtrees.                                                                                                                                                                                                                                                                                                             |
| LEVEL                | 0-31         | 0       | <p>Specifies the backup level.</p> <p>Level 0 copies the entire data set. Incremental backup levels, specified by values above 0, copy all files (new or modified) since the last incremental backup. For example, a level 1 backs up new or modified files since the level 0 backup, a level 2 backs up new or modified files since the level 1 backup, and so on.</p>                                    |
| LIST                 | Y or N       | N       | Lists the backed-up file names and inode numbers without actually restoring the data.                                                                                                                                                                                                                                                                                                                      |
| LIST_QTREES          | Y or N       | N       | Lists the backed-up qtrees without actually restoring the data.                                                                                                                                                                                                                                                                                                                                            |
| MULTI_SUBTREE_NAMES  | string       | none    | <p>Specifies that the backup is a multiple subtree backup.</p> <p>Multiple subtrees are specified in the string, which is a newline-separated, null-terminated list of subtree names. Subtrees are specified by path names relative to their common root directory, which must be specified as the last element of the list.</p> <p>If you use this variable, you must also use the DMP_NAME variable.</p> |

| Environment variable | Valid values | Default | Description                                                                                                                                                                                                                                                                                                                      |
|----------------------|--------------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NDMP_UNICODE_FH      | Y or N       | N       | <p>Specifies that a Unicode name is included in addition to the NFS name of the file in the file history information.</p> <p>This option is not used by most backup applications and should not be set unless the backup application is designed to receive these additional file names. The HIST variable must also be set.</p> |
| NO_ACLS              | Y or N       | N       | Specifies that ACLs must not be copied when backing up data.                                                                                                                                                                                                                                                                     |

| Environment variable | Valid values | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|--------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NON_QUOTA_TREE       | Y or N       | N       | <p>Specifies that files and directories in qtrees must be ignored when backing up data.</p> <p>When set to Y, items in qtrees in the data set specified by the FILESYSTEM variable are not backed up. This variable has an effect only if the FILESYSTEM variable specifies an entire volume. The NON_QUOTA_TREE variable only works on a level 0 backup and does not work if the MULTI_SUBTREE NAMES variable is specified.</p> <p> Files or directories specified to be excluded for backup are not excluded if you set NON_QUOTA_TREE to Y simultaneously.</p> |
| NOWRITE              | Y or N       | N       | <p>Specifies that the restore operation must not write data to the disk.</p> <p>This variable is used for debugging.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Environment variable | Valid values | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------|--------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RECURSIVE            | Y or N       | Y       | <p>Specifies that directory entries during a DAR restore be expanded.</p> <p>The DIRECT and ENHANCED_DAR_ENABLED environment variables must be enabled (set to Y) as well. If the RECURSIVE variable is disabled (set to N), only the permissions and ACLs for all the directories in the original source path are restored from tape, not the contents of the directories. If the RECURSIVE variable is set to N or the RECOVER_FULL_PATHS variable is set to Y, the recovery path must end with the original path.</p> <p>If the RECURSIVE variable is disabled and if there is more than one recovery path, all of the recovery paths must be contained within the longest of the recovery paths. Otherwise, an error message is displayed.</p> <p>For example, the following are valid recovery paths because all of the recovery paths are within foo/dir1/deepdir/my file:</p> |

| Environment variable | Valid values | Default | Description                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|--------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RECOVER_FULL_PATHS   | Y or N       | N       | <p>Specifies that the full recovery path will have their permissions and ACLs restored after the DAR.</p> <p>DIRECT and ENHANCED_DAR_ENABLED must be enabled (set to Y) as well. If RECOVER_FULL_PATHS is set to Y, the recovery path must end with the original path. If directories already exist on the destination volume, their permissions and ACLs will not be restored from tape.</p> |
| UPDATE               | Y or N       | Y       | Updates the metadata information to enable LEVEL based incremental backup.                                                                                                                                                                                                                                                                                                                    |

== Environment variables supported for SMTape

| Environment variable | Valid values | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|--------------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BASE_DATE            | DUMP_DATE    | -1      | <p>Specifies the start date for incremental backups.</p> <p>BASE_DATE is a string representation of the reference Snapshot identifiers. Using the BASE_DATE string, SMTape locates the reference Snapshot copy.</p> <p>BASE_DATE is not required for baseline backups. For an incremental backup, the value of the DUMP_DATE variable from the previous baseline or incremental backup is assigned to the BASE_DATE variable.</p> <p>The backup application assigns the DUMP_DATE value from a previous SMTape baseline or incremental backup.</p> |
| DUMP_DATE            | return_value | none    | <p>At the end of an SMTape backup, DUMP_DATE contains a string identifier that identifies the Snapshot copy used for that backup. This Snapshot copy could be used as the reference Snapshot copy for a subsequent incremental backup.</p> <p>The resulting value of DUMP_DATE is used as the BASE_DATE value for subsequent incremental backups.</p>                                                                                                                                                                                              |

| Environment variable   | Valid values                                            | Default | Description                                                                                                                                                                                                                                                                                               |
|------------------------|---------------------------------------------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SMTAPE_BACKUP_SET_ID   | string                                                  | none    | <p>Identifies the sequence of incremental backups associated with the baseline backup.</p> <p>Backup set ID is a 128-bit unique ID that is generated during a baseline backup. The backup application assigns this ID as the input to the SMTAPE_BACKUP_SET_ID variable during an incremental backup.</p> |
| SMTAPE_SNAPSHOT_NAME   | Any valid Snapshot copy that is available in the volume | Invalid | <p>When the SMTAPE_SNAPSHOT_NAME variable is set to a Snapshot copy, that Snapshot copy and its older Snapshot copies are backed up to tape.</p> <p>For incremental backup, this variable specifies incremental Snapshot copy. The BASE_DATE variable provides the baseline Snapshot copy.</p>            |
| SMTAPE_DELETE_SNAPSHOT | Y or N                                                  | N       | <p>For a Snapshot copy created automatically by SMTape, when the SMTAPE_DELETE_SNAPSHOT variable is set to Y, then after the backup operation is complete, SMTape deletes this Snapshot copy. However, a Snapshot copy created by the backup application will not be deleted.</p>                         |
| SMTAPE_BREAK_MIRROR    | Y or N                                                  | N       | <p>When the SMTAPE_BREAK_MIRROR variable is set to Y, the volume of type DP is changed to a RW volume after a successful restore.</p>                                                                                                                                                                     |

```
= Common NDMP tape backup topologies
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/
```

NDMP supports a number of topologies and configurations between backup applications and storage systems or other NDMP servers providing data (file systems) and tape services.

#### == Storage system-to-local-tape

In the simplest configuration, a backup application backs up data from a storage system to a tape subsystem attached to the storage system. The NDMP control connection exists across the network boundary. The NDMP data connection that exists within the storage system between the data and tape services is called an NDMP local configuration.

#### == Storage system-to-tape attached to another storage system

A backup application can also back up data from a storage system to a tape library (a medium changer with one or more tape drives) attached to another storage system. In this case, the NDMP data connection between the data and tape services is provided by a TCP or TCP/IPv6 network connection. This is called an NDMP three-way storage system-to-storage system configuration.

#### == Storage system-to-network-attached tape library

NDMP-enabled tape libraries provide a variation of the three-way configuration. In this case, the tape library attaches directly to the TCP/IP network and communicates with the backup application and the storage system through an internal NDMP server.

#### == Storage system-to-data server-to-tape or data server-to-storage system-to-tape

NDMP also supports storage system-to-data-server and data-server-to-storage system three-way configurations, although these variants are less widely deployed. Storage system-to-server allows storage system data to be backed up to a tape library attached to the backup application host or to another data server system. The server-to-storage system configuration allows server data to be backed up to a storage system-attached tape library.

```
= Supported NDMP authentication methods
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/
```

You can specify an authentication method to allow NDMP connection requests. ONTAP supports two methods for authenticating NDMP access to a storage system: plaintext and challenge.

In node-scoped NDMP mode, both challenge and plaintext are enabled by default. However, you cannot disable challenge. You can enable and disable plaintext. In the plaintext authentication method, the login password is transmitted as clear text.

In the storage virtual machine (SVM)-scoped NDMP mode, by default the authentication method is challenge. Unlike the node-scoped NDMP mode, in this mode you can enable and disable both plaintext and challenge authentication methods.

= NDMP extensions supported by ONTAP

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

NDMP v4 provides a mechanism for creating NDMP v4 protocol extensions without modifying the core NDMP v4 protocol. You should be aware of the NDMP v4 extensions that are supported by ONTAP.

The following NDMP v4 extensions are supported by ONTAP:

- Cluster Aware Backup (CAB)

This extension is supported only in the SVM-scoped NDMP mode.

- Connection Address Extension (CAE) for IPv6 support
- Extension class 0x2050

This extension supports restartable backup operations and Snapshot Management Extensions.

The NDMP\_SNAP\_RECOVER message, which is part of the Snapshot Management Extensions, is used to initiate a recovery operation and to transfer the recovered data from a local Snapshot copy to a local file system location. In ONTAP, this message allows the recovery of volumes and regular files only.

The NDMP\_SNAP\_DIR\_LIST message enables you to browse through the Snapshot copies of a volume. If a nondisruptive operation takes place while a browsing operation is in progress, the backup application must reinitiate the browsing operation.

= NDMP restartable backup extension for a dump supported by ONTAP

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can use the NDMP restartable backup extension (RBE) functionality to restart a backup from a known checkpoint in the data stream before the failure.

= What enhanced DAR functionality is

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can use the enhanced direct access recovery (DAR) functionality for directory DAR and DAR of files and NT streams. By default, enhanced DAR functionality is enabled.

Enabling enhanced DAR functionality might impact the backup performance because an offset map has to be

created and written onto tape. You can enable or disable enhanced DAR in both the node-scoped and storage virtual machine (SVM)-scoped NDMP modes.

= Scalability limits for NDMP sessions

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You must be aware of the maximum number of NDMP sessions that can be established simultaneously on storage systems of different system memory capacities. This maximum number depends on the system memory of a storage system.

The limits mentioned in the following table are for the NDMP server. The limits mentioned in the section “Scalability limits for dump backup and restore sessions” are for the dump and restore session.

#### [Scalability limits for dump backup and restore sessions](#)

| System memory of a storage system                  | Maximum number of NDMP sessions |
|----------------------------------------------------|---------------------------------|
| Less than 16 GB                                    | 8                               |
| Greater than or equal to 16 GB but less than 24 GB | 20                              |
| Greater than or equal to 24 GB                     | 36                              |

You can obtain the system memory of your storage system by using the `sysconfig -a` command (available through the nodeshell). For more information about using this command, see the man pages.

= About NDMP for FlexGroup volumes

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

Beginning with ONTAP 9.7, NDMP is supported on FlexGroup volumes.

Beginning with ONTAP 9.7, the `ndmpcopy` command is supported for data transfer between FlexVol and FlexGroup volumes.

If you revert from ONTAP 9.7 to an earlier version, the incremental transfer information of the previous transfers is not retained and therefore, you must perform a baseline copy after reverting.

Beginning with ONTAP 9.8, the following NDMP features are supported on FlexGroup volumes:

- The NDMP\_SNAP\_RECOVER message in the extension class 0x2050 can be used for recovering individual files in a FlexGroup volume.
- NDMP restartable backup extension (RBE) is supported for FlexGroup volumes.
- Environment variables EXCLUDE and MULTI\_SUBTREE\_NAMES are supported for FlexGroup volumes.

= About NDMP with SnapLock volumes

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

Creating multiple copies of regulated data provides you with redundant recovery scenarios, and by using NDMP dump and restore, it's possible to preserve the write once, read many (WORM) characteristics of source files on a SnapLock volume.

WORM attributes on the files in a SnapLock volume are preserved when backing up, restoring and copying data; however, WORM attributes are enforced only when restoring to a SnapLock volume. If a backup from a SnapLock volume is restored to a volume other than a SnapLock volume, the WORM attributes are preserved but are ignored and are not enforced by ONTAP.

You can manage NDMP at the node level by using NDMP options and commands. You can modify the NDMP options by using the `options` command. You must use NDMP-specific credentials to access a storage system to perform tape backup and restore operations.

For more information about the `options` command, see the man pages.

You can use the `system services ndmp` commands to manage NDMP at a node level. Some of these commands are deprecated and will be removed in a future major release.

You can use the following NDMP commands only at the advanced privilege level:

- `system services ndmp service terminate`
- `system services ndmp service start`
- `system services ndmp service stop`
- `system services ndmp log start`
- `system services ndmp log stop`

| Stop logging for the specified NDMP session          | system services ndmp log stop*               |

- These commands are deprecated and will be removed in a future major release.

For more information about these commands, see the man pages for the `system services ndmp` commands.

```
= User authentication in a node-scoped NDMP mode
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/
```

In the node-scoped NDMP mode, you must use NDMP specific credentials to access a storage system in order to perform tape backup and restore operations.

The default user ID is “root”. Before using NDMP on a node, you must ensure that you change the default NDMP password associated with the NDMP user. You can also change the default NDMP user ID.

```

You can manage NDMP on a per SVM basis by using the NDMP options and commands. You can modify the NDMP options by using the `vserver services ndmp modify` command. In the SVM-scoped NDMP mode, user authentication is integrated with the role-based access control mechanism.

You can add NDMP in the allowed or disallowed protocols list by using the `vserver modify` command. By default, NDMP is in the allowed protocols list. If NDMP is added to the disallowed protocols list, NDMP sessions cannot be established.

You can control the LIF type on which an NDMP data connection is established by using the `-preferred-interface-role` option. During an NDMP data connection establishment, NDMP chooses an IP address that belongs to the LIF type as specified by this option. If the IP addresses do not belong to any of these LIF types, then the NDMP data connection cannot be established. For more information about the `-preferred-interface-role` option, see the man pages.

For more information about the `vserver services ndmp modify` command, see the man pages.

= What Cluster Aware Backup extension does

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/./media/

CAB (Cluster Aware Backup) is an NDMP v4 protocol extension. This extension enables the NDMP server to establish a data connection on a node that owns a volume. This also enables the backup application to determine if volumes and tape devices are located on the same node in a cluster.

To enable the NDMP server to identify the node that owns a volume and to establish a data connection on such a node, the backup application must support the CAB extension. CAB extension requires the backup application to inform the NDMP server about the volume to be backed up or restored prior to establishing the data connection. This allows the NDMP server to determine the node that hosts the volume and appropriately establish the data connection.

With the CAB extension supported by the backup application, the NDMP server provides affinity information about volumes and tape devices. Using this affinity information, the backup application can perform a local backup instead of a three-way backup if a volume and tape device are located on the same node in a cluster.

= Availability of volumes and tape devices for backup and restore on different LIF types

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/./media/

You can configure a backup application to establish an NDMP control connection on any of the LIF types in a cluster. In the storage virtual machine (SVM)-scoped NDMP mode, you can determine the availability of volumes and tape devices for backup and restore operations depending upon these LIF types and the status of the CAB extension.

The following tables show the availability of volumes and tape devices for NDMP control connection LIF types and the status of the CAB extension:

== Availability of volumes and tape devices when CAB extension is not supported by the backup application

| <b>NDMP control connection LIF type</b> | <b>Volumes available for backup or restore</b>                               | <b>Tape devices available for backup or restore</b>                |
|-----------------------------------------|------------------------------------------------------------------------------|--------------------------------------------------------------------|
| Node-management LIF                     | All volumes hosted by a node                                                 | Tape devices connected to the node hosting the node-management LIF |
| Data LIF                                | Only volumes that belong to the SVM hosted by a node that hosts the data LIF | None                                                               |
| Cluster-management LIF                  | All volumes hosted by a node that hosts the cluster-management LIF           | None                                                               |
| Intercluster LIF                        | All volumes hosted by a node that hosts the intercluster LIF                 | Tape devices connected to the node hosting the intercluster LIF    |

== Availability of volumes and tape devices when CAB extension is supported by the backup application

| <b>NDMP control connection LIF type</b> | <b>Volumes available for backup or restore</b>             | <b>Tape devices available for backup or restore</b>                |
|-----------------------------------------|------------------------------------------------------------|--------------------------------------------------------------------|
| Node-management LIF                     | All volumes hosted by a node                               | Tape devices connected to the node hosting the node-management LIF |
| Data LIF                                | All volumes that belong to the SVM that hosts the data LIF | None                                                               |
| Cluster-management LIF                  | All volumes in the cluster                                 | All tape devices in the cluster                                    |
| Intercluster LIF                        | All volumes in the cluster                                 | All tape devices in the cluster                                    |

= What affinity information is

:icons: font

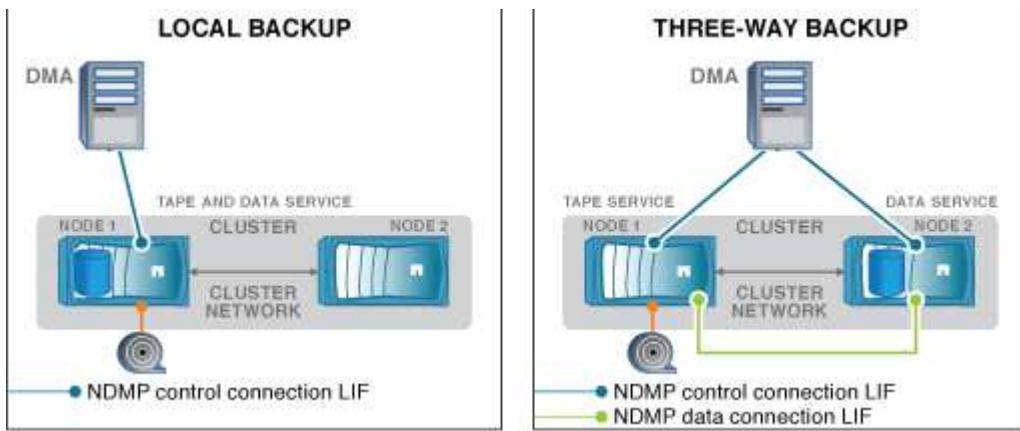

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

With the backup application being CAB aware, the NDMP server provides unique location information about volumes and tape devices. Using this affinity information, the backup application can perform a local backup instead of a three-way backup if a volume and a tape device share the same affinity.

If the NDMP control connection is established on a node management LIF, cluster management LIF, or an intercluster LIF, the backup application can use the affinity information to determine if a volume and tape device are located on the same node and then perform either a local or a three-way backup or restore operation. If the NDMP control connection is established on a data LIF, then the backup application always performs a three-way backup.

## == Local NDMP backup and Three-way NDMP backup

Using the affinity information about volumes and tape devices, the DMA (backup application) performs a local NDMP backup on the volume and tape device located on Node 1 in the cluster. If the volume moves from Node 1 to Node 2, affinity information about the volume and tape device changes. Hence, for a subsequent backup the DMA performs a three-way NDMP backup operation. This ensures continuity of the backup policy for the volume irrespective of the node to which the volume is moved to.

= NDMP server supports secure control connections in SVM-scoped mode

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

A secure control connection can be established between the Data Management Application (DMA) and NDMP server by using secure sockets (SSL/TLS) as the communication mechanism. This SSL communication is based on the server certificates. The NDMP server listens on port 30000 (assigned by IANA for “ndmps” service).

After establishing the connection from the client on this port, the standard SSL handshake ensues where the server presents the certificate to the client. When the client accepts the certificate, the SSL handshake is complete. After this process is complete, all of the communication between the client and the server is encrypted. The NDMP protocol workflow remains exactly as before. The secure NDMP connection requires server-side certificate authentication only. A DMA can choose to establish a connection either by connecting to the secure NDMP service or the standard NDMP service.

By default, secure NDMP service is disabled for a storage virtual machine (SVM). You can enable or disable the secure NDMP service on a given SVM by using the `vserver services ndmp modify -vserver vserver -is-secure-control-connection-enabled [true|false]` command.

= NDMP data connection types

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

In the storage virtual machine (SVM)-scoped NDMP mode, the supported NDMP data connection types depend on the NDMP control connection LIF type and the status of the CAB extension. This NDMP data connection type indicates whether you can perform a

local or a three-way NDMP backup or restore operation.

You can perform a three-way NDMP backup or restore operation over a TCP or TCP/IPv6 network. The following tables show the NDMP data connection types based on the NDMP control connection LIF type and the status of the CAB extension.

== NDMP data connection type when CAB extension is supported by the backup application

| NDMP control connection LIF type | NDMP data connection type |
|----------------------------------|---------------------------|
| Node-management LIF              | LOCAL, TCP, TCP/IPv6      |
| Data LIF                         | TCP, TCP/IPv6             |
| Cluster-management LIF           | LOCAL, TCP, TCP/IPv6      |
| Intercluster LIF                 | LOCAL, TCP, TCP/IPv6      |

== NDMP data connection type when CAB extension is not supported by the backup application

| NDMP control connection LIF type | NDMP data connection type |
|----------------------------------|---------------------------|
| Node-management LIF              | LOCAL, TCP, TCP/IPv6      |
| Data LIF                         | TCP, TCP/IPv6             |
| Cluster-management LIF           | TCP, TCP/IPv6             |
| Intercluster LIF                 | LOCAL, TCP, TCP/IPv6      |

## Related information

[What Cluster Aware Backup extension does](#)

[Network management](#)

= User authentication in the SVM-scoped NDMP mode

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

In the storage virtual machine (SVM)-scoped NDMP mode, NDMP user authentication is integrated with role-based access control. In the SVM context, the NDMP user must have either the “vsadmin” or “vsadmin-backup” role. In a cluster context, the NDMP user must have either the “admin” or “backup” role.

Apart from these pre-defined roles, a user account associated with a custom role can also be used for NDMP authentication provided that the custom role has the “vserver services ndmp” folder in its command directory and the access level of the folder is not “none”. In this mode, you must generate an NDMP password for a given user account, which is created through role-based access control. Cluster users in an admin or backup

role can access a node-management LIF, a cluster-management LIF, or an intercluster LIF. Users in a vsadmin-backup or vsadmin role can access only the data LIF for that SVM. Therefore, depending on the role of a user, the availability of volumes and tape devices for backup and restore operations vary.

This mode also supports user authentication for NIS and LDAP users. Therefore, NIS and LDAP users can access multiple SVMs with a common user ID and password. However, NDMP authentication does not support Active Directory users.

In this mode, a user account must be associated with the SSH application and the “User password” authentication method.

= Generate an NDMP-specific password for NDMP users

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

In the storage virtual machine (SVM)-scoped NDMP mode, you must generate a password for a specific user ID. The generated password is based on the actual login password for the NDMP user. If the actual login password changes, you must generate the NDMP-specific password again.

## Steps

1. Use the vserver services ndmp generate-password command to generate an NDMP-specific password.

You can use this password in any current or future NDMP operation that requires password input.

From the storage virtual machine (SVM, formerly known as Vserver) context, you can generate NDMP passwords for users belonging only to that SVM.

The following example shows how to generate an NDMP-specific password for a user ID user1:

```
cluster1::vserver services ndmp> generate-password -vserver vs1 -user
user1

Vserver: vs1
User: user1
Password: jWZiNt57huPOoD8d
```

2. If you change the password to your regular storage system account, repeat this procedure to obtain your new NDMP-specific password.

= How tape backup and restore operations are affected during disaster recovery in MetroCluster configuration

:icons: font  
:relative\_path: ./tape-backup/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can perform tape backup and restore operations simultaneously during disaster recovery in a MetroCluster configuration. You must understand how these operations are affected during disaster recovery.

If tape backup and restore operations are performed on a volume of anSVM in a disaster recovery relationship, then you can continue performing incremental tape backup and restore operations after a switchover and switchback.

= About dump engine for FlexVol volumes

= About dump engine for FlexVol volumes

:icons: font  
:relative\_path: ./tape-backup/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

Dump is a Snapshot copy based backup and recovery solution from ONTAP that helps you to back up files and directories from a Snapshot copy to a tape device and restore the backed up data to a storage system.

You can back up your file system data, such as directories, files, and their associated security settings, to a tape device by using the dump backup. You can back up an entire volume, an entire qtree, or a subtree that is neither an entire volume nor an entire qtree.

You can perform a dump backup or restore by using NDMP-compliant backup applications.

When you perform a dump backup, you can specify the Snapshot copy to be used for a backup. If you do not specify a Snapshot copy for the backup, the dump engine creates a Snapshot copy for the backup. After the backup operation is completed, the dump engine deletes this Snapshot copy.

You can perform level-0, incremental, or differential backups to tape by using the dump engine.

After reverting to a release earlier than Data ONTAP 8.3, you must perform a baseline backup operation before performing an incremental backup operation.

[Upgrade, revert, or downgrade](#)

= How a dump backup works

:icons: font  
:relative\_path: ./tape-backup/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

A dump backup writes file system data from disk to tape using a predefined process. You can back up a volume, a qtree, or a subtree that is neither an entire volume nor an entire qtree.

The following table describes the process that ONTAP uses to back up the object indicated by the dump path:

| Stage | Action                                                                                                                                                                                                       |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1     | For less than full volume or full qtree backups, ONTAP traverses directories to identify the files to be backed up. If you are backing up an entire volume or qtree, ONTAP combines this stage with Stage 2. |
| 2     | For a full volume or full qtree backup, ONTAP identifies the directories in the volumes or qtrees to be backed up.                                                                                           |
| 3     | ONTAP writes the directories to tape.                                                                                                                                                                        |
| 4     | ONTAP writes the files to tape.                                                                                                                                                                              |
| 5     | ONTAP writes the ACL information (if applicable) to tape.                                                                                                                                                    |

The dump backup uses a Snapshot copy of your data for the backup. Therefore, you do not have to take the volume offline before initiating the backup.

The dump backup names each Snapshot copy it creates as `snapshot_for_backup.n`, where n is an integer starting at 0. Each time the dump backup creates a Snapshot copy, it increments the integer by 1. The integer is reset to 0 after the storage system is rebooted. After the backup operation is completed, the dump engine deletes this Snapshot copy.

When ONTAP performs multiple dump backups simultaneously, the dump engine creates multiple Snapshot copies. For example, if ONTAP is running two dump backups simultaneously, you find the following Snapshot copies in the volumes from which data is being backed up: `snapshot_for_backup.0` and `snapshot_for_backup.1`.

When you are backing up from a Snapshot copy, the dump engine does not create an additional Snapshot copy.

= Types of data that the dump engine backs up

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

The dump engine enables you to back up data to tape to guard against disasters or controller disruptions. In addition to backing up data objects such as files, directories, qtrees, or entire volumes, the dump engine can back up many types of information about each file. Knowing the types of data that the dump engine can back up and the restrictions to take into consideration can help you plan your approach to disaster recovery.

In addition to backing up data in files, the dump engine can back up the following information about each file, as applicable:

- UNIX GID, owner UID, and file permissions
- UNIX access, creation, and modification time
- File type

- File size
- DOS name, DOS attributes, and creation time
- Access control lists (ACLs) with 1,024 access control entries (ACEs)
- Qtree information
- Junction paths

Junction paths are backed up as symbolic links.

- LUN and LUN clones

You can back up an entire LUN object; however, you cannot back up a single file within the LUN object. Similarly, you can restore an entire LUN object but not a single file within the LUN.

The dump engine backs up LUN clones as independent LUNs.

- VM-aligned files

Backup of VM-aligned files is not supported in releases earlier than Data ONTAP 8.1.2.

When a snapshot-backed LUN clone is transitioned from Data ONTAP operating in 7-Mode to ONTAP, it becomes an inconsistent LUN. The dump engine does not back up inconsistent LUNs.

When you restore data to a volume, client I/O is restricted on the LUNs being restored. The LUN restriction is removed only when the dump restore operation is complete. Similarly, during a SnapMirror single file or LUN restore operation, client I/O is restricted on both files and LUNs being restored. This restriction is removed only when the single file or LUN restore operation is complete. If a dump backup is performed on a volume on which a dump restore or SnapMirror single file or LUN restore operation is being performed, then the files or LUNs that have client I/O restriction are not included in the backup. These files or LUNs are included in a subsequent backup operation if the client I/O restriction is removed.

A LUN running on Data ONTAP 8.3 that is backed up to tape can be restored only to 8.3 and later releases and not to an earlier release. If the LUN is restored to an earlier release, then the LUN is restored as a file.

When you back up a SnapVault secondary volume or a volume SnapMirror destination to tape, only the data on the volume is backed up. The associated metadata is not backed up. Therefore, when you try to restore the volume, only the data on that volume is restored. Information about the volume SnapMirror relationships is not available in the backup and therefore is not restored.

If you dump a file that has only Windows NT permissions and restore it to a UNIX-style qtree or volume, the file gets the default UNIX permissions for that qtree or volume.

If you dump a file that has only UNIX permissions and restore it to an NTFS-style qtree or volume, the file gets the default Windows permissions for that qtree or volume.

Other dumps and restores preserve permissions.

You can back up VM-aligned files and the `vm-align-sector` option. For more information about VM-aligned files, see [Logical storage management](#).

= What increment chains are  
:icons: font  
:relative\_path: ./tape-backup/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

An increment chain is a series of incremental backups of the same path. Because you can specify any level of backup at any time, you must understand increment chains to be able to perform backups and restores effectively. You can perform 31 levels of incremental backup operations.

There are two types of increment chains:

- A consecutive increment chain, which is a sequence of incremental backups that starts with level 0 and is raised by 1 at each subsequent backup.
- A nonconsecutive increment chain, where incremental backups skip levels or have levels that are out of sequence, such as 0, 2, 3, 1, 4, or more commonly 0, 1, 1, 1 or 0, 1, 2, 1, 2.

Incremental backups are based on the most recent lower-level backup. For example, the sequence of backup levels 0, 2, 3, 1, 4 provides two increment chains: 0, 2, 3 and 0, 1, 4. The following table explains the bases of the incremental backups:

| <b>Backup order</b> | <b>Increment level</b> | <b>Increment chain</b> | <b>Base</b>                                                                                                      | <b>Files backed up</b>                                                                                                 |
|---------------------|------------------------|------------------------|------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| 1                   | 0                      | Both                   | Files on the storage system                                                                                      | All files in the backup path                                                                                           |
| 2                   | 2                      | 0, 2, 3                | Level-0 backup                                                                                                   | Files in the backup path created since the level-0 backup                                                              |
| 3                   | 3                      | 0, 2, 3                | Level-2 backup                                                                                                   | Files in the backup path created since the level-2 backup                                                              |
| 4                   | 1                      | 0, 1, 4                | Level-0 backup, because this is the most recent level that is lower than the level-1 backup                      | Files in the backup path created since the level-0 backup, including files that are in the level-2 and level-3 backups |
| 5                   | 4                      | 0, 1, 4                | The level-1 backup, because it is a lower level and is more recent than the level-0, level-2, or level-3 backups | Files created since the level-1 backup                                                                                 |

= What the blocking factor is  
:icons: font  
:relative\_path: ./tape-backup/

```
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/
```

A tape block is 1,024 bytes of data. During a tape backup or restore, you can specify the number of tape blocks that are transferred in each read/write operation. This number is called the *blocking factor*.

You can use a blocking factor from 4 to 256. If you plan to restore a backup to a system other than the system that did the backup, the restore system must support the blocking factor that you used for the backup. For example, if you use a blocking factor of 128, the system on which you restore that backup must support a blocking factor of 128.

During an NDMP backup, the MOVER\_RECORD\_SIZE determines the blocking factor. ONTAP allows a maximum value of 256 KB for MOVER\_RECORD\_SIZE.

= When to restart a dump backup

:icons: font

:relative\_path: ./tape-backup/

```
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/
```

A dump backup sometimes does not finish because of internal or external errors, such as tape write errors, power outages, accidental user interruptions, or internal inconsistency on the storage system. If your backup fails for one of these reasons, you can restart it.

You can choose to interrupt and restart a backup to avoid periods of heavy traffic on the storage system or to avoid competition for other limited resources on the storage system, such as a tape drive. You can interrupt a long backup and restart it later if a more urgent restore (or backup) requires the same tape drive. Restartable backups persist across reboots. You can restart an aborted backup to tape only if the following conditions are true:

- The aborted backup is in phase IV.
- All of the associated Snapshot copies that were locked by the dump command are available.
- The file history must be enabled.

When such a dump operation is aborted and left in a restartable state, the associated Snapshot copies are locked. These Snapshot copies are released after the backup context is deleted. You can view the list of backup contexts by using the vserver services ndmp restartable backup show command.

```

cluster::> vserver services ndmpd restartable-backup show

= How a dump restore works

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

A dump restore writes file system data from tape to disk using a predefined process.

The process in the following table shows how the dump restore works:

| Stage | Action                                                            |
|-------|-------------------------------------------------------------------|
| 1     | ONTAP catalogs the files that need to be extracted from the tape. |
| 2     | ONTAP creates directories and empty files.                        |

| Stage | Action                                                                                            |
|-------|---------------------------------------------------------------------------------------------------|
| 3     | ONTAP reads a file from tape, writes it to disk, and sets the permissions (including ACLs) on it. |
| 4     | ONTAP repeats stages 2 and 3 until all the specified files are copied from the tape.              |

= Types of data that the dump engine restores

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

When a disaster or controller disruption occurs, the dump engine provides multiple methods for you to recover all of the data that you backed up, from single files, to file attributes, to entire directories. Knowing the types of data that dump engine can restore and when to use which method of recovery can help minimize downtime.

You can restore data to an online mapped LUN. However, host applications cannot access this LUN until the restore operation is complete. After the restore operation is complete, the host cache of the LUN data should be flushed to provide coherency with the restored data.

The dump engine can recover the following data:

- Contents of files and directories
- UNIX file permissions
- ACLs

If you restore a file that has only UNIX file permissions to an NTFS qtree or volume, the file has no Windows NT ACLs. The storage system uses only the UNIX file permissions on this file until you create a Windows NT ACL on it.

If you restore ACLs backed up from storage systems running Data ONTAP 8.2 to storage systems running Data ONTAP 8.1.x and earlier that have an ACE limit lower than 1,024, a default ACL is restored.

- Qtree information

Qtree information is used only if a qtree is restored to the root of a volume. Qtree information is not used if a qtree is restored to a lower directory, such as /vs1/vol1/subdir/lowerdir, and it ceases to be a qtree.

- All other file and directory attributes
- Windows NT streams
- LUNs
  - A LUN must be restored to a volume level or a qtree level for it to remain as a LUN.

If it is restored to a directory, it is restored as a file because it does not contain any valid metadata.

- A 7-Mode LUN is restored as a LUN on an ONTAP volume.

- A 7-Mode volume can be restored to an ONTAP volume.
- VM-aligned files restored to a destination volume inherit the VM-align properties of the destination volume.
- The destination volume for a restore operation might have files with mandatory or advisory locks.

While performing restore operation to such a destination volume, the dump engine ignores these locks.

= Considerations before restoring data

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

You can restore backed-up data to its original path or to a different destination. If you are restoring backed-up data to a different destination, you must prepare the destination for the restore operation.

Before restoring data either to its original path or to a different destination, you must have the following information and meet the following requirements:

- The level of the restore
- The path to which you are restoring the data
- The blocking factor used during the backup
- If you are doing an incremental restore, all tapes must be in the backup chain
- A tape drive that is available and compatible with the tape to be restored from

Before restoring data to a different destination, you must perform the following operations:

- If you are restoring a volume, you must create a new volume.
- If you are restoring a qtree or a directory, you must rename or move files that are likely to have the same names as files you are restoring.

In ONTAP 9, qtree names support the Unicode format. The earlier releases of ONTAP do not support this format. If a qtree with Unicode names in ONTAP 9 is copied to an earlier release of ONTAP using the `ndmpcopy` command or through restoration from a backup image in a tape, the qtree is restored as a regular directory and not as a qtree with Unicode format.

If a restored file has the same name as an existing file, the existing file is overwritten by the restored file. However, the directories are not overwritten.

To rename a file, directory, or qtree during restore without using DAR, you must set the EXTRACT environment variable to E.

== Required space on the destination storage system

You require about 100 MB more space on the destination storage system than the amount of data to be restored.

The restore operation checks for volume space and inode availability on the destination volume when the restore operation starts. Setting the FORCE environment variable to Y causes the restore operation to skip the checks for volume space and inode availability on the destination path. If there is not enough volume space or inodes available on the destination volume, the restore operation recovers as much data allowed by the destination volume space and inode availability. The restore operation stops when there is no more volume space or inodes left.

= Scalability limits for dump backup and restore sessions

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You must be aware of the maximum number of dump backup and restore sessions that can be performed simultaneously on storage systems of different system memory capacities. This maximum number depends on the system memory of a storage system.

The limits mentioned in the following table are for the dump or restore engine. The limits mentioned in the scalability limits for NDMP sessions are for the NDMP server, which are higher than the engine limits.

| System memory of a storage system                  | Total number of dump backup and restore sessions |
|----------------------------------------------------|--------------------------------------------------|
| Less than 16 GB                                    | 4                                                |
| Greater than or equal to 16 GB but less than 24 GB | 16                                               |
| Greater than or equal to 24 GB                     | 32                                               |

If you use `ndmpcopy` command to copy data within storage systems, two NDMP sessions are established, one for dump backup and the other for dump restore.

You can obtain the system memory of your storage system by using the `sysconfig -a` command (available through the nodeshell). For more information about using this command, see the man pages.

### [Scalability limits for NDMP sessions](#)

= Tape backup and restore support between Data ONTAP operating in 7-Mode and ONTAP

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You can restore data backed up from a storage system operating in 7-Mode or running ONTAP to a storage system either operating in 7-Mode or running ONTAP.

The following tape backup and restore operations are supported between Data ONTAP operating in 7-Mode and ONTAP:

- Backing up a 7-Mode volume to a tape drive connected to a storage system running ONTAP
- Backing up an ONTAP volume to a tape drive connected to a 7-Mode system

- Restoring backed-up data of a 7-Mode volume from a tape drive connected to a storage system running ONTAP
- Restoring backed-up data of an ONTAP volume from a tape drive connected to a 7-Mode system
- Restoring a 7-Mode volume to an ONTAP volume

- A 7-Mode LUN is restored as a LUN on an ONTAP volume.
- You should retain the ONTAP LUN identifiers when restoring a 7-Mode LUN to an existing ONTAP LUN.

- Restoring an ONTAP volume to a 7-Mode volume

An ONTAP LUN is restored as a regular file on a 7-Mode volume.

= Delete restartable contexts

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

If you want to start a backup instead of restarting a context, you can delete the context.

### About this task

You can delete a restartable context using the `vserver services ndmp restartable-backup delete` command by providing the SVM name and the context ID.

### Steps

1. Delete a restartable context:

```
vserver services ndmp restartable-backup delete -vserver vserver-name -context
-id context_identifier.
```

```

cluster::> vserver services ndmpd restartable-backup show
Vserver Context Identifier Is Cleanup Pending?

vserver1 330e6739-0179-11e6-a299-005056bb4bc9 false
vserver1 481025c1-0179-11e6-a299-005056bb4bc9 false
vserver2 5cf10132-0179-11e6-a299-005056bb4bc9 false
3 entries were displayed.

cluster::>
cluster::> vserver services ndmp restartable-backup delete -vserver
vserver1 -context-id 481025c1-0179-11e6-a299-005056bb4bc9

cluster::> vserver services ndmpd restartable-backup show
Vserver Context Identifier Is Cleanup Pending?

vserver1 330e6739-0179-11e6-a299-005056bb4bc9 false
vserver2 5cf10132-0179-11e6-a299-005056bb4bc9 false
3 entries were displayed.

cluster::>"
```

= How dump works on a SnapVault secondary volume

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..../media/

You can perform tape backup operations on data that is mirrored on the SnapVault secondary volume. You can back up only the data that is mirrored on the SnapVault secondary volume to tape, and not the SnapVault relationship metadata.

When you break the data protection mirror relationship (`snapmirror break`) or when a SnapMirror resynchronization occurs, you must always perform a baseline backup.

= How dump works with storage failover and ARL operations

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..../media/

Before you perform dump backup or restore operations, you should understand how these operations work with storage failover (takeover and giveback) or aggregate relocation (ARL) operations. The `-override-veto`s option determines the behavior of dump engine during a storage failover or ARL operation.

When a dump backup or restore operation is running and the `-override-veto`s option is set to `false`, a user-initiated storage failover or ARL operation is stopped. However, if the `-override-veto`s option is set to `true`, then the storage failover or ARL operation is continued and the dump backup or restore operation is aborted. When a storage failover or ARL operation is automatically initiated by the storage system, an active

dump backup or restore operation is always aborted. You cannot restart dump backup and restore operations even after storage failover or ARL operations complete.

## == Dump operations when CAB extension is supported

If the backup application supports CAB extension, you can continue performing incremental dump backup and restore operations without reconfiguring backup policies after a storage failover or ARL operation.

## == Dump operations when CAB extension is not supported

If the backup application does not support CAB extension, you can continue performing incremental dump backup and restore operations if you migrate the LIF configured in the backup policy to the node that hosts the destination aggregate. Otherwise, after the storage failover and ARL operation, you must perform a baseline backup prior to performing the incremental backup operation.

For storage failover operations, the LIF configured in the backup policy must be migrated to the partner node.

= How dump works with volume move

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

Tape backup and restore operations and volume move can run in parallel until the final cutover phase is attempted by the storage system. After this phase, new tape backup and restore operations are not allowed on the volume that is being moved. However, the current operations continue to run until completion.

The following table describes the behavior of tape backup and restore operations after the volume move operation:

| If you are performing tape backup and restore operations in the...                                       | Then...                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| storage virtual machine (SVM) scoped NDMP mode when CAB extension is supported by the backup application | You can continue performing incremental tape backup and restore operations on read/write and read-only volumes without reconfiguring backup policies.                                                                                                                                                                                            |
| SVM-scoped NDMP mode when CAB extension is not supported by the backup application                       | You can continue performing incremental tape backup and restore operations on read/write and read-only volumes if you migrate the LIF configured in the backup policy to the node that hosts the destination aggregate. Otherwise, after the volume move, you must perform a baseline backup before performing the incremental backup operation. |

When a volume move occurs, if the volume belonging to a different SVM on the destination node has the same name as that of the moved volume, then you cannot perform incremental backup operations of the moved volume.

## Related information

### [ONTAP concepts](#)

= How dump works when a FlexVol volume is full

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

Before performing an incremental dump backup operation, you must ensure that there is sufficient free space in the FlexVol volume.

If the operation fails, you must increase the free space in the Flex Vol volume either by increasing its size or by deleting the Snapshot copies. Then perform the incremental backup operation again.

= How dump works when volume access type changes

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

When a SnapMirror destination volume or a SnapVault secondary volume changes state from read/write to read-only or from read-only to read/write, you must perform a baseline tape backup or restore operation.

SnapMirror destination and SnapVault secondary volumes are read-only volumes. If you perform tape backup and restore operations on such volumes, you must perform a baseline backup or restore operation whenever the volume changes state from read-only to read/write or from read/write to read-only.

## Related information

### [ONTAP concepts](#)

= How dump works with SnapMirror single file or LUN restore

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

Before you perform dump backup or restore operations on a volume to which a single file or LUN is restored by using SnapMirror technology, you must understand how dump operations work with a single file or LUN restore operation.

During a SnapMirror single file or LUN restore operation, client I/O is restricted on the file or LUN being restored. When the single file or LUN restore operation finishes, the I/O restriction on the file or LUN is removed. If a dump backup is performed on a volume to which a single file or LUN is restored, then the file or LUN that has client I/O restriction is not included in the dump backup. In a subsequent backup operation, this file or LUN is backed up to tape after the I/O restriction is removed.

You cannot perform a dump restore and a SnapMirror single file or LUN restore operation simultaneously on the same volume.

= How dump backup and restore operations are affected in MetroCluster configurations

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

Before you perform dump backup and restore operations in a MetroCluster configuration, you must understand how dump operations are affected when a switchover or switchback operation occurs.

== Dump backup or restore operation followed by switchover

Consider two clusters: cluster 1 and cluster 2. During a dump backup or restore operation on cluster 1, if a switchover is initiated from cluster 1 to cluster 2, then the following occurs:

- If the value of the `override-vetoed` option is `false`, then the switchover is aborted and the backup or restore operation continues.
- If the value of the option is `true`, then the dump backup or restore operation is aborted and the switchover continues.

== Dump backup or restore operation followed by switchback

A switchover is performed from cluster 1 to cluster 2 and a dump backup or restore operation is initiated on cluster 2. The dump operation backs up or restores a volume that is located on cluster 2. At this point, if a switchback is initiated from cluster 2 to cluster 1, then the following occurs:

- If the value of the `override-vetoed` option is `false`, then the switchback is cancelled and the backup or restore operation continues.
- If the value of the option is `true`, then the backup or restore operation is aborted and the switchback continues.

== Dump backup or restore operation initiated during a switchover or switchback

During a switchover from cluster 1 to cluster 2, if a dump backup or restore operation is initiated on cluster 1, then the backup or restore operation fails and the switchover continues.

During a switchback from cluster 2 to cluster 1, if a dump backup or restore operation is initiated from cluster 2, then the backup or restore operation fails and the switchback continues.

= About SMTape engine for FlexVol volumes

= About SMTape engine for FlexVol volumes

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

SMTape is a disaster recovery solution from ONTAP that backs up blocks of data to tape. You can use SMTape to perform volume backups to tapes. However, you cannot perform a backup at the qtree or subtree level. SMTape supports baseline, differential, and incremental backups. SMTape does not require a license.

You can perform an SMTape backup and restore operation by using an NDMP-compliant backup application. You can choose SMTape to perform backup and restore operations only in the storage virtual machine (SVM)

scoped NDMP mode.

Reversion process is not supported when an SMTape backup or restore session is in progress. You must wait until the session finishes or you must abort the NDMP session.

Using SMTape, you can back up 255 Snapshot copies. For subsequent baseline, incremental, or differential backups, you must delete older backed-up Snapshot copies.

Before performing a baseline restore, the volume to which data is being restored must be of type DP and this volume must be in the restricted state. After a successful restore, this volume is automatically online. You can perform subsequent incremental or differential restores on this volume in the order in which the backups were performed.

= Use Snapshot copies during SMTape backup

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..../media/

You should understand how Snapshot copies are used during an SMTape baseline backup and an incremental backup. There are also considerations to keep in mind while performing a backup using SMTape.

== Baseline backup

While performing a baseline backup, you can specify the name of the Snapshot copy to be backed up to tape. If no Snapshot copy is specified, then depending on the access type of the volume (read/write or read-only), either a Snapshot copy is created automatically or existing Snapshot copies are used. When you specify a Snapshot copy for the backup, all the Snapshot copies older than the specified Snapshot copy are also backed up to tape.

If you do not specify a Snapshot copy for the backup, the following occurs:

- For a read/write volume, a Snapshot copy is created automatically.

The newly created Snapshot copy and all the older Snapshot copies are backed up to tape.

- For a read-only volume, all the Snapshot copies, including the latest Snapshot copy, are backed up to tape.

Any new Snapshot copies created after the backup is started are not backed up.

== Incremental backup

For SMTape incremental or differential backup operations, the NDMP-compliant backup applications create and manage the Snapshot copies.

You must always specify a Snapshot copy while performing an incremental backup operation. For a successful incremental backup operation, the Snapshot copy backed up during the previous backup operation (baseline or incremental) must be on the volume from which the backup is performed. To ensure that you use this backed-up Snapshot copy, you must consider the Snapshot policy assigned on this volume while configuring the backup policy.

== Considerations on SMTape backups on SnapMirror destinations

- A data protection mirror relationship creates temporary Snapshot copies on the destination volume for replication.

You should not use these Snapshot copies for SMTape backup.

- If a SnapMirror update occurs on a destination volume in a data protection mirror relationship during an SMTape backup operation on the same volume, then the Snapshot copy that is backed up by SMTape must not be deleted on the source volume.

During the backup operation, SMTape locks the Snapshot copy on the destination volume and if the corresponding Snapshot copy is deleted on the source volume, then the subsequent SnapMirror update operation fails.

- You should not use these Snapshot copies during incremental backup.

= SMTape capabilities

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

SMTape capabilities such as backup of Snapshot copies, incremental and differential backups, preservation of deduplication and compression features on restored volumes, and tape seeding help you optimize your tape backup and restore operations.

SMTape provides the following capabilities:

- Provides a disaster recovery solution
- Enables incremental and differential backups
- Backs up Snapshot copies
- Enables backup and restore of deduplicated volumes and preserves deduplication on the restored volumes
- Backs up compressed volumes and preserves compression on the restored volumes
- Enables tape seeding

SMTape supports the blocking factor in multiples of 4 KB, in the range of 4 KB through 256 KB.

You can restore data to volumes created across up to two major consecutive ONTAP releases only.

= Features not supported in SMTape

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

SMTape does not support restartable backups and verification of backed-up files.

= Scalability limits for SMTape backup and restore sessions

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

While performing SMTape backup and restore operations through NDMP or CLI (tape

seeding), you must be aware of the maximum number of SMTape backup and restore sessions that can be performed simultaneously on storage systems with different system memory capacities. This maximum number depends on the system memory of a storage system.

SMTape backup and restore sessions scalability limits are different from NDMP session limits and dump session limits.

| System memory of the storage system                | Total number of SMTape backup and restore sessions |
|----------------------------------------------------|----------------------------------------------------|
| Less than 16 GB                                    | 6                                                  |
| Greater than or equal to 16 GB but less than 24 GB | 16                                                 |
| Greater than or equal to 24 GB                     | 32                                                 |

You can obtain the system memory of your storage system by using the `sysconfig -a` command (available through the nodeshell). For more information about using this command, see the man pages.

= What tape seeding is

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

Tape seeding is an SMTape functionality that helps you initialize a destination FlexVol volume in a data protection mirror relationship.

Tape seeding enables you to establish a data protection mirror relationship between a source system and a destination system over a low-bandwidth connection.

Incremental mirroring of Snapshot copies from the source to the destination is feasible over a low bandwidth connection. However, an initial mirroring of the base Snapshot copy takes a long time over a low-bandwidth connection. In such cases, you can perform an SMTape backup of the source volume to a tape and use the tape to transfer the initial base Snapshot copy to the destination. You can then set up incremental SnapMirror updates to the destination system using the low-bandwidth connection.

= How SMTape works with volume move

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

SMTape backup operations and volume move operations can run in parallel until the storage system attempts the final cutover phase. After this phase, new SMTape backup operations cannot run on the volume that is being moved. However, the current operations continue to run until completion.

Before the cutover phase for a volume is started, the volume move operation checks for active SMTape backup operations on the same volume. If there are active SMTape backup operations, then the volume move operation moves into a cutover deferred state and allows the SMTape backup operations to complete. After these backup operations are completed, you must manually restart the volume move operation.

If the backup application supports CAB extension, you can continue performing incremental tape backup and restore operations on read/write and read-only volumes without reconfiguring backup policies.

Baseline restore and volume move operations cannot be performed simultaneously; however, incremental restore can run in parallel with volume move operations, with the behavior similar to that of SMTape backup operations during volume move operations.

## Related information

= How SMTape works with volume rehost operations

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

SMTape operations cannot commence when a volume rehost operation is in progress on a volume. When a volume is involved in a volume rehost operation, SMTape sessions should not be started on that volume.

If any volume rehost operation is in progress, then SMTape backup or restore fails. If an SMTape backup or restore is in progress, then volume rehost operations fail with an appropriate error message. This condition

applies to both NDMP-based and CLI-based backup or restore operations.

= How NDMP backup policy are affected during ADB

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

When the automatic data balancer (ADB) is enabled, the balancer analyzes the usage statistics of aggregates to identify the aggregate that has exceeded the configured high-threshold usage percentage.

After identifying the aggregate that has exceeded the threshold, the balancer identifies a volume that can be moved to aggregates residing in another node in the cluster and attempts to move that volume. This situation affects the backup policy configured for this volume because if the data management application (DMA) is not CAB aware, then the user has to reconfigure the backup policy and run the baseline backup operation.

If the DMA is CAB aware and the backup policy has been configured using specific interface, then the ADB is not affected.

= How SMTape backup and restore operations are affected in MetroCluster configurations

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

Before you perform SMTape backup and restore operations in a MetroCluster configuration, you must understand how SMTape operations are affected when a switchover or switchback operation occurs.

== SMTape backup or restore operation followed by switchover

Consider two clusters: cluster 1 and cluster 2. During an SMTape backup or restore operation on cluster 1, if a switchover is initiated from cluster 1 to cluster 2, then the following occurs:

- If the value of the `-override-veto`s option is `false`, then the switchover process is aborted and the backup or restore operation continues.
- If the value of the option is `true`, then the SMTape backup or restore operation is aborted and the switchover process continues.

== SMTape backup or restore operation followed by switchback

A switchover is performed from cluster 1 to cluster 2 and an SMTape backup or restore operation is initiated on cluster 2. The SMTape operation backs up or restores a volume that is located on cluster 2. At this point, if a switchback is initiated from cluster 2 to cluster 1, then the following occurs:

- If the value of the `-override-veto`s option is `false`, then the switchback process is aborted and the backup or restore operation continues.
- If the value of the option is `true`, then the backup or restore operation is aborted and the switchback process continues.

== SMTape backup or restore operation initiated during a switchover or switchback

During a switchover process from cluster 1 to cluster 2, if an SMTape backup or restore operation is initiated on

cluster 1, then the backup or restore operation fails and the switchover continues.

During a switchback process from cluster 2 to cluster 1, if an SMTape backup or restore operation is initiated from cluster 2, then the backup or restore operation fails and the switchback continues.

= Monitor tape backup and restore operations for FlexVol volumes

= Monitor tape backup and restore operations for FlexVol volumes overview

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can view the event log files to monitor the tape backup and restore operations. ONTAP automatically logs significant backup and restore events and the time at which they occur in a log file named `backup` in the controller's `/etc/log/` directory. By default, event logging is set to on.

You might want to view event log files for the following reasons:

- Checking whether a nightly backup was successful
- Gathering statistics on backup operations
- For using the information in past event log files to help diagnose problems with backup and restore operations

Once every week, the event log files are rotated. The `/etc/log/backup` file is renamed to `/etc/log/backup.0`, the `/etc/log/backup.0` file is renamed to `/etc/log/backup.1`, and so on. The system saves the log files for up to six weeks; therefore, you can have up to seven message files (`/etc/log/backup.[0-5]` and the current `/etc/log/backup` file).

= Access the event log files

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can access the event log files for tape backup and restore operations in the `/etc/log/` directory by using the `rdfile` command at the nodeshell. You can view these event log files to monitor tape backup and restore operations.

## About this task

With additional configurations, such as an access-control role with access to the `spi` web service or a user account set up with the `http` access method, you can also use a web browser to access these log files.

## Steps

1. To access the nodeshell, enter the following command:

```
node run -node node_name
```

`node_name` is the name of the node.

2. To access the event log files for tape backup and restore operations, enter the following command:

```
rdfile /etc/log/backup
```

= What the dump and restore event log message format is

= Dump and restore event log message format overview

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

For each dump and restore event, a message is written to the backup log file.

The format of the dump and restore event log message is as follows:

```
type timestamp identifier event (event_info)
```

The following list describes the fields in the event log message format:

- Each log message begins with one of the type indicators described in the following table:

| Type | Description   |
|------|---------------|
| log  | Logging event |
| dmp  | Dump event    |
| rst  | Restore event |

- timestamp shows the date and time of the event.

- The identifier field for a dump event includes the dump path and the unique ID for the dump. The identifier field for a restore event uses only the restore destination path name as a unique identifier. Logging-related event messages do not include an identifier field.

= What logging events are

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

The event field of a message that begins with a log specifies the beginning of a logging or the end of a logging.

It contains one of the events shown in the following table:

| Event         | Description                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------|
| Start_Logging | Indicates the beginning of logging or that logging has been turned back on after being disabled. |
| Stop_Logging  | Indicates that logging has been turned off.                                                      |

= What dump events are

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

The event field for a dump event contains an event type followed by event-specific information within parentheses.

The following table describes the events, their descriptions, and the related event information that might be recorded for a dump operation:

| Event        | Description                                                 | Event information                                                |
|--------------|-------------------------------------------------------------|------------------------------------------------------------------|
| Start        | NDMP dump is started                                        | Dump level and the type of dump                                  |
| End          | Dumps completed successfully                                | Amount of data processed                                         |
| Abort        | The operation is cancelled                                  | Amount of data processed                                         |
| Options      | Specified options are listed                                | All options and their associated values, including NDMP options  |
| Tape_open    | The tape is open for read/write                             | The new tape device name                                         |
| Tape_close   | The tape is closed for read/write                           | The tape device name                                             |
| Phase-change | A dump is entering a new processing phase                   | The new phase name                                               |
| Error        | A dump has encountered an unexpected event                  | Error message                                                    |
| Snapshot     | A Snapshot copy is created or located                       | The name and time of the Snapshot copy                           |
| Base_dump    | A base dump entry in the internal metafile has been located | The level and time of the base dump (for incremental dumps only) |

= What restore events are

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/../encryption-at-rest/..media/

The event field for a restore event contains an event type followed by event-specific information in parentheses.

The following table provides information about the events, their descriptions, and the related event information that can be recorded for a restore operation:

| Event        | Description                                | Event information                                               |
|--------------|--------------------------------------------|-----------------------------------------------------------------|
| Start        | NDMP restore is started                    | Restore level and the type of restore                           |
| End          | Restores completed successfully            | Number of files and amount of data processed                    |
| Abort        | The operation is cancelled                 | Number of files and amount of data processed                    |
| Options      | Specified options are listed               | All options and their associated values, including NDMP options |
| Tape_open    | The tape is open for read/write            | The new tape device name                                        |
| Tape_close   | The tape is closed for read/write          | The tape device name                                            |
| Phase-change | Restore is entering a new processing phase | The new phase name                                              |
| Error        | Restore encounters an unexpected event     | Error message                                                   |

= Enabling or disabling event logging

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/../encryption-at-rest/..media/

You can turn the event logging on or off.

## Steps

1. To enable or disable event logging, enter the following command at the clustershell:

```
options -option_name backup.log.enable -option-value {on | off}
```

on turns event logging on.

off turns event logging off.

Event logging is turned on by default.

= Error messages for tape backup and restore of FlexVol volumes

= Backup and restore error messages

= Resource limitation: no available thread

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

- **Message**

Resource limitation: no available thread

- **Cause**

The maximum number of active local tape I/O threads is currently in use. You can have a maximum of 16 active local tape drives.

- **Corrective action**

Wait for some tape jobs to finish before starting a new backup or restore job.

= Tape reservation preempted

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

- **Message**

Tape reservation preempted

- **Cause**

The tape drive is in use by another operation or the tape has been closed prematurely.

- **Corrective action**

Ensure that the tape drive is not in use by another operation and that the DMA application has not aborted the job and then retry.

= Could not initialize media

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

- **Message**

Could not initialize media

- **Cause**

You might get this error for one of the following reasons:

- The tape drive used for the backup is corrupt or damaged.

- The tape does not contain the complete backup or is corrupt.
- The maximum number of active local tape I/O threads is currently in use.

You can have a maximum of 16 active local tape drives.

- **Corrective action**

- If the tape drive is corrupt or damaged, retry the operation with a valid tape drive.
- If the tape does not contain the complete backup or is corrupt, you cannot perform the restore operation.
- If tape resources are not available, wait for some of the backup or restore jobs to finish and then retry the operation.

= Maximum number of allowed dumps or restores (maximum session limit) in progress

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Maximum number of allowed dumps or restores (*maximum session limit*) in progress

- **Cause**

The maximum number of backup or restore jobs is already running.

- **Corrective action**

Retry the operation after some of the currently running jobs have finished.

= Media error on tape write

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Media error on tape write

- **Cause**

The tape used for the backup is corrupted.

- **Corrective action**

Replace the tape and retry the backup job.

= Tape write failed

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Tape write failed

- **Cause**

The tape used for the backup is corrupted.

- **Corrective action**

Replace the tape and retry the backup job.

= Tape write failed - new tape encountered media error

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Tape write failed - new tape encountered media error

- **Cause**

The tape used for the backup is corrupted.

- **Corrective action**

Replace the tape and retry the backup.

= Tape write failed - new tape is broken or write protected

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Tape write failed - new tape is broken or write protected

- **Cause**

The tape used for the backup is corrupted or write-protected.

- **Corrective action**

Replace the tape and retry the backup.

= Tape write failed - new tape is already at the end of media

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Tape write failed - new tape is already at the end of media

- **Cause**

There is not enough space on the tape to complete the backup.

- **Corrective action**

Replace the tape and retry the backup.

= Tape write error

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Tape write error - The previous tape had less than the required minimum capacity, size MB, for this tape operation. The operation should be restarted from the beginning

- **Cause**

The tape capacity is insufficient to contain the backup data.

- **Corrective action**

Use tapes with larger capacity and retry the backup job.

= Media error on tape read

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Media error on tape read

- **Cause**

The tape from which data is being restored is corrupted and might not contain the complete backup data.

- **Corrective action**

If you are sure that the tape has the complete backup, retry the restore operation. If the tape does not contain the complete backup, you cannot perform the restore operation.

= Tape read error

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Tape read error

- **Cause**

The tape drive is damaged or the tape does not contain the complete backup.

- **Corrective action**

If the tape drive is damaged, use another tape drive. If the tape does not contain the complete backup, you cannot restore the data.

= Already at the end of tape

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Already at the end of tape

- **Cause**

The tape does not contain any data or must be rewound.

- **Corrective action**

If the tape does not contain data, use the tape that contains the backup and retry the restore job. Otherwise, rewind the tape and retry the restore job.

= Tape record size is too small. Try a larger size.

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Tape record size is too small. Try a larger size.

- **Cause**

The blocking factor specified for the restore operation is smaller than the blocking factor that was used during the backup.

- **Corrective action**

Use the same blocking factor that was specified during the backup.

= Tape record size should be block\_size1 and not block\_size2

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Tape record size should be block\_size1 and not block\_size2

- **Cause**

The blocking factor specified for the local restore is incorrect.

- **Corrective action**

Retry the restore job with `block_size1` as the blocking factor.

= Tape record size must be in the range between 4KB and 256KB

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

- **Message**

Tape record size must be in the range between 4KB and 256KB

- **Cause**

The blocking factor specified for the backup or restore operation is not within the permitted range.

- **Corrective action**

Specify a blocking factor in the range of 4 KB to 256 KB.

= NDMP error messages

= Network communication error

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

- **Message**

Network communication error

- **Cause**

Communication to a remote tape in an NDMP three-way connection has failed.

- **Corrective action**

Check the network connection to the remote mover.

= Message from Read Socket: `error_string`

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

- **Message**

Message from Read Socket: `error_string`

- **Cause**

Restore communication from the remote tape in NDMP 3-way connection has errors.

- **Corrective action**

Check the network connection to the remote mover.

= Message from Write Dirnet: error\_string

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

- **Message**

Message from Write Dirnet: error\_string

- **Cause**

Backup communication to a remote tape in an NDMP three-way connection has an error.

- **Corrective action**

Check the network connection to the remote mover.

= Read Socket received EOF

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

- **Message**

Read Socket received EOF

- **Cause**

Attempt to communicate with a remote tape in an NDMP three-way connection has reached the End Of File mark. You might be attempting a three-way restore from a backup image with a larger block size.

- **Corrective action**

Specify the correct block size and retry the restore operation.

= ndmpd invalid version number: version\_number ``

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

- **Message**

ndmpd invalid version number: version\_number

- **Cause**

The NDMP version specified is not supported by the storage system.

- **Corrective action**

Specify NDMP version 4.

```
= ndmpd session session_ID not active
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/
```

- **Message**

```
ndmpd session session_ID not active
```

- **Cause**

The NDMP session might not exist.

- **Corrective action**

Use the `ndmpd status` command to view the active NDMP sessions.

```
= Could not obtain vol ref for Volume volume_name
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/
```

- **Message**

```
Could not obtain vol ref for Volume vol_name
```

- **Cause**

The volume reference could not be obtained because the volume might be in use by other operations.

- **Corrective action**

Retry the operation later.

```
= Data connection type ["NDMP4_ADDR_TCP"|"NDMP4_ADDR_TCP_IPv6"] not supported for ["IPv6"|"IPv4"]
control connections
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/
```

- **Message**

```
Data connection type ["NDMP4_ADDR_TCP"|"NDMP4_ADDR_TCP_IPv6"] not supported
for ["IPv6"|"IPv4"] control connections
```

- **Cause**

In node-scoped NDMP mode, the NDMP data connection established must be of the same network

address type (IPv4 or IPv6) as the NDMP control connection.

- **Corrective action**

Contact your backup application vendor.

= DATA LISTEN: CAB data connection prepare precondition error

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

DATA LISTEN: CAB data connection prepare precondition error

- **Cause**

NDMP data listen fails when the backup application has negotiated the CAB extension with the NDMP server and there is a mismatch in the specified NDMP data connection address type between the NDMP\_CAB\_DATA\_CONN\_PREPARE and the NDMP\_DATA\_LISTEN messages.

- **Corrective action**

Contact your backup application vendor.

= DATA CONNECT: CAB data connection prepare precondition error

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

DATA CONNECT: CAB data connection prepare precondition error

- **Cause**

NDMP data connect fails when the backup application has negotiated the CAB extension with the NDMP server and there is a mismatch in the specified NDMP data connection address type between the NDMP\_CAB\_DATA\_CONN\_PREPARE and the NDMP\_DATA\_CONNECT messages.

- **Corrective action**

Contact your backup application vendor.

= Error:show failed: Cannot get password for user '<username>'

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Error: show failed: Cannot get password for user '<username>'

- **Cause**

Incomplete user account configuration for NDMP

- **Corrective action**

Ensure that the user account is associated with the SSH access method and the authentication method is user password.

= Dump error messages

= Destination volume is read-only

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Destination volume is read-only

- **Cause**

The path to which the restore operation is attempted to is read-only.

- **Corrective action**

Try restoring the data to a different location.

= Destination qtree is read-only

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Destination qtree is read-only

- **Cause**

The qtree to which the restore is attempted to is read-only.

- **Corrective action**

Try restoring the data to a different location.

= Dumps temporarily disabled on volume, try again

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Dumps temporarily disabled on volume, try again

- **Cause**

NDMP dump backup is attempted on a SnapMirror destination volume that is part of either a `snapmirror break` or a `snapmirror resync` operation.

- **Corrective action**

Wait for the `snapmirror break` or `snapmirror resync` operation to finish and then perform the dump operation.

Whenever the state of a SnapMirror destination volume changes from read/write to read-only or from read-only to read/write, you must perform a baseline backup.

= NFS labels not recognized

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Error: Aborting: dump encountered NFS security labels in the file system

- **Cause**

NFS security labels are supported Beginning with ONTAP 9.9.1 when NFSv4.2 is enabled. However, NFS security labels are not currently recognized by the dump engine. If it encounters any NFS security labels on the files, directories, or any special files in any format of dump, the dump fails.

- **Corrective action**

Verify that no files or directories have NFS security labels.

= No files were created

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

No files were created

- **Cause**

A directory DAR was attempted without enabling the enhanced DAR functionality.

- **Corrective action**

Enable the enhanced DAR functionality and retry the DAR.

= Restore of the file <file name> failed

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Restore of the file file name failed

- **Cause**

When a DAR (Direct Access Recovery) of a file whose file name is the same as that of a LUN on the destination volume is performed, then the DAR fails.

- **Corrective action**

Retry DAR of the file.

= Truncation failed for src inode <inode number>...

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/../media/

- **Message**

Truncation failed for src inode <inode number>. Error <error number>. Skipping inode.

- **Cause**

Inode of a file is deleted when the file is being restored.

- **Corrective action**

Wait for the restore operation on a volume to complete before using that volume.

= Unable to lock a snapshot needed by dump

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/../media/

- **Message**

Unable to lock a snapshot needed by dump

- **Cause**

The Snapshot copy specified for the backup is not available.

- **Corrective action**

Retry the backup with a different Snapshot copy.

Use the `snap list` command to see the list of available Snapshot copies.

= Unable to locate bitmap files

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/../encryption-at-rest/..media/

- **Message**

Unable to locate bitmap files

- **Cause**

The bitmap files required for the backup operation might have been deleted. In this case, the backup cannot be restarted.

- **Corrective action**

Perform the backup again.

= Volume is temporarily in a transitional state

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/../encryption-at-rest/..media/

- **Message**

Volume is temporarily in a transitional state

- **Cause**

The volume being backed up is temporarily in an unmounted state.

- **Corrective action**

Wait for some time and perform the backup again.

= SMTape error messages

= Chunks out of order

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/../encryption-at-rest/..media/

- **Message**

Chunks out of order

- **Cause**

The backup tapes are not being restored in the correct sequence.

- **Corrective action**

Retry the restore operation and load the tapes in the correct sequence.

= Chunk format not supported

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Chunk format not supported

- **Cause**

The backup image is not of SMTape.

- **Corrective action**

If the backup image is not of SMTape, retry the operation with a tape that has the SMTape backup.

= Failed to allocate memory

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Failed to allocate memory

- **Cause**

The system has run out of memory.

- **Corrective action**

Retry the job later when the system is not too busy.

= Failed to get data buffer

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Failed to get data buffer

- **Cause**

The storage system ran out of buffers.

- **Corrective action**

Wait for some storage system operations to finish and then retry the job.

= Failed to find snapshot

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Failed to find snapshot

- **Cause**

The Snapshot copy specified for the backup is unavailable.

- **Corrective action**

Check if the specified Snapshot copy is available. If not, retry with the correct Snapshot copy.

= Failed to create snapshot

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

- **Message**

Failed to create snapshot

- **Cause**

The volume already contains the maximum number of Snapshot copies.

- **Corrective action**

Delete some Snapshot copies and then retry the backup operation.

= Failed to lock snapshot

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

- **Message**

Failed to lock snapshot

- **Cause**

The Snapshot copy is either in use or has been deleted.

- **Corrective action**

If the Snapshot copy is in use by another operation, wait for that operation to finish and then retry the backup. If the Snapshot copy has been deleted, you cannot perform the backup.

= Failed to delete snapshot

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

- **Message**

Failed to delete snapshot

- **Cause**

The auto Snapshot copy could not be deleted because it is in use by other operations.

- **Corrective action**

Use the `snap` command to determine the status of the Snapshot copy. If the Snapshot copy is not required, delete it manually.

= Failed to get latest snapshot

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Failed to get latest snapshot

- **Cause**

The latest Snapshot copy might not exist because the volume is being initialized by SnapMirror.

- **Corrective action**

Retry after initialization is complete.

= Failed to load new tape

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Failed to load new tape

- **Cause**

Error in tape drive or media.

- **Corrective action**

Replace the tape and retry the operation.

= Failed to initialize tape

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Failed to initialize tape

- **Cause**

You might get this error message for one of the following reasons:

- The backup image is not of SMTape.
- The tape blocking factor specified is incorrect.
- The tape is corrupt or damaged.
- The wrong tape is loaded for restore.

• **Corrective action**

- If the backup image is not of SMTape, retry the operation with a tape that has SMTape backup.
- If the blocking factor is incorrect, specify the correct blocking factor and retry the operation.
- If the tape is corrupt, you cannot perform the restore operation.
- If the wrong tape is loaded, retry the operation with the correct tape.

= Failed to initialize restore stream

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

• **Message**

Failed to initialize restore stream

• **Cause**

You might get this error message for one of the following reasons:

- The backup image is not of SMTape.
- The tape blocking factor specified is incorrect.
- The tape is corrupt or damaged.
- The wrong tape is loaded for restore.

• **Corrective action**

- If the backup image is not of SMTape, retry the operation with a tape that has the SMTape backup.
- If the blocking factor is incorrect, specify the correct blocking factor and retry the operation.
- If the tape is corrupt, you cannot perform the restore operation.
- If the wrong tape is loaded, retry the operation with the correct tape.

= Failed to read backup image

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

• **Message**

Failed to read backup image

• **Cause**

The tape is corrupt.

- **Corrective action**

If the tape is corrupt, you cannot perform the restore operation.

= Image header missing or corrupted

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

- **Message**

Image header missing or corrupted

- **Cause**

The tape does not contain a valid SMTape backup.

- **Corrective action**

Retry with a tape containing a valid backup.

= Internal assertion

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

- **Message**

Internal assertion

- **Cause**

There is an internal SMTape error.

- **Corrective action**

Report the error and send the etc/log/backup file to technical support.

= Invalid backup image magic number

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

- **Message**

Invalid backup image magic number

- **Cause**

The backup image is not of SMTape.

- **Corrective action**

If the backup image is not of SMTape, retry the operation with a tape that has the SMTape backup.

= Invalid backup image checksum  
:icons: font  
:relative\_path: ./tape-backup/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

- **Message**

Invalid backup image checksum

- **Cause**

The tape is corrupt.

- **Corrective action**

If the tape is corrupt, you cannot perform the restore operation.

= Invalid input tape  
:icons: font  
:relative\_path: ./tape-backup/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

- **Message**

Invalid input tape

- **Cause**

The signature of the backup image is not valid in the tape header. The tape has corrupted data or does not contain a valid backup image.

- **Corrective action**

Retry the restore job with a valid backup image.

= Invalid volume path  
:icons: font  
:relative\_path: ./tape-backup/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

- **Message**

Invalid volume path

- **Cause**

The specified volume for the backup or restore operation is not found.

- **Corrective action**

Retry the job with a valid volume path and volume name.

= Mismatch in backup set ID  
:icons: font

```
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/
```

- **Message**

Mismatch in backup set ID

- **Cause**

The tape loaded during a tape change is not a part of the backup set.

- **Corrective action**

Load the correct tape and retry the job.

= Mismatch in backup time stamp

:icons: font

```
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/
```

- **Message**

Mismatch in backup time stamp

- **Cause**

The tape loaded during a tape change is not a part of the backup set.

- **Corrective action**

Use the `smtape restore -h` command to verify the header information of a tape.

= Job aborted due to shutdown

:icons: font

```
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/
```

- **Message**

Job aborted due to shutdown

- **Cause**

The storage system is being rebooted.

- **Corrective action**

Retry the job after the storage system reboots.

= Job aborted due to Snapshot autodelete

:icons: font

```
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/
```

- **Message**

Job aborted due to Snapshot autodelete

- **Cause**

The volume does not have enough space and has triggered the automatic deletion of Snapshot copies.

- **Corrective action**

Free up space in the volume and retry the job.

= Tape is currently in use by other operations

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

- **Message**

Tape is currently in use by other operations

- **Cause**

The tape drive is in use by another job.

- **Corrective action**

Retry the backup after the currently active job is finished.

= Tapes out of order

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

- **Message**

Tapes out of order

- **Cause**

The first tape of the tape sequence for the restore operation does not have the image header.

- **Corrective action**

Load the tape with the image header and retry the job.

= Transfer failed (Aborted due to MetroCluster operation)

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

- **Message**

Transfer failed (Aborted due to MetroCluster operation)

- **Cause**

The SMTape operation is aborted because of a switchover or switchback operation.

- **Corrective action**

Perform the SMTape operation after the switchover or switchback operation finishes.

= Transfer failed (ARL initiated abort)

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Transfer failed (ARL initiated abort)

- **Cause**

While an SMTape operation is in progress if an aggregate relocation is initiated, then the SMTape operation is aborted.

- **Corrective action**

Perform the SMTape operation after the aggregate relocation operation finishes.

= Transfer failed (CFO initiated abort)

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Transfer failed (CFO initiated abort)

- **Cause**

The SMTape operation is aborted because of a storage failover (takeover and giveback) operation of a CFO aggregate.

- **Corrective action**

Perform the SMTape operation after the storage failover of the CFO aggregate finishes.

= Transfer failed (SFO initiated abort)

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Transfer failed (SFO initiated abort)

- **Cause**

The SMTape operation is aborted because of a storage failover (takeover and giveback) operation.

- **Corrective action**

Perform the SMTape operation after the storage failover (takeover and giveback) operation finishes.

= Underlying aggregate under migration

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Underlying aggregate under migration

- **Cause**

If an SMTape operation is initiated on an aggregate that is under migration (storage failover or aggregate relocation), then the SMTape operation fails.

- **Corrective action**

Perform the SMTape operation after the aggregate migration finishes.

= Volume is currently under migration

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Volume is currently under migration

- **Cause**

Volume migration and SMTape backup cannot run simultaneously.

- **Corrective action**

Retry the backup job after the volume migration is complete.

= Volume offline

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

- **Message**

Volume offline

- **Cause**

The volume being backed up is offline.

- **Corrective action**

Bring the volume online and retry the backup.

= Volume not restricted

:icons: font

:relative\_path: ./tape-backup/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

- **Message**

Volume not restricted

- **Cause**

The destination volume to which data is being restored is not restricted.

- **Corrective action**

Restrict the volume and retry the restore operation.

= NDMP configuration

= NDMP configuration overview

:icons: font

:relative\_path: ./ndmp/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You can quickly configure an ONTAP 9 cluster to use the Network Data Management Protocol (NDMP) to back up data directly to tape using a third-party backup application.

If the backup application supports Cluster Aware Backup (CAB), you can configure NDMP as *SVM-scoped* or *node-scoped*:

- SVM-scoped at the cluster (admin SVM) level enables you to back up all volumes hosted across different nodes of the cluster. SVM-scoped NDMP is recommended where possible.
- Node-scoped NDMP enables you to back up all the volumes hosted on that node.

If the backup application does not support CAB, you must use node-scoped NDMP.

SVM-scoped and node-scoped NDMP are mutually exclusive; they cannot be configured on the same cluster.

Node-scoped NDMP is deprecated in ONTAP 9.

Learn more about [Cluster Aware Backup \(CAB\)](#).

Before configuring NDMP, verify the following:

- You have a third-party backup application (also called a Data Management Application or DMA).
- You are a cluster administrator.

- Tape devices and an optional media server are installed.
- Tape devices are connected to the cluster through a Fibre Channel (FC) switch and not directly attached.
- At least one tape device has a logical unit number (LUN) of 0.

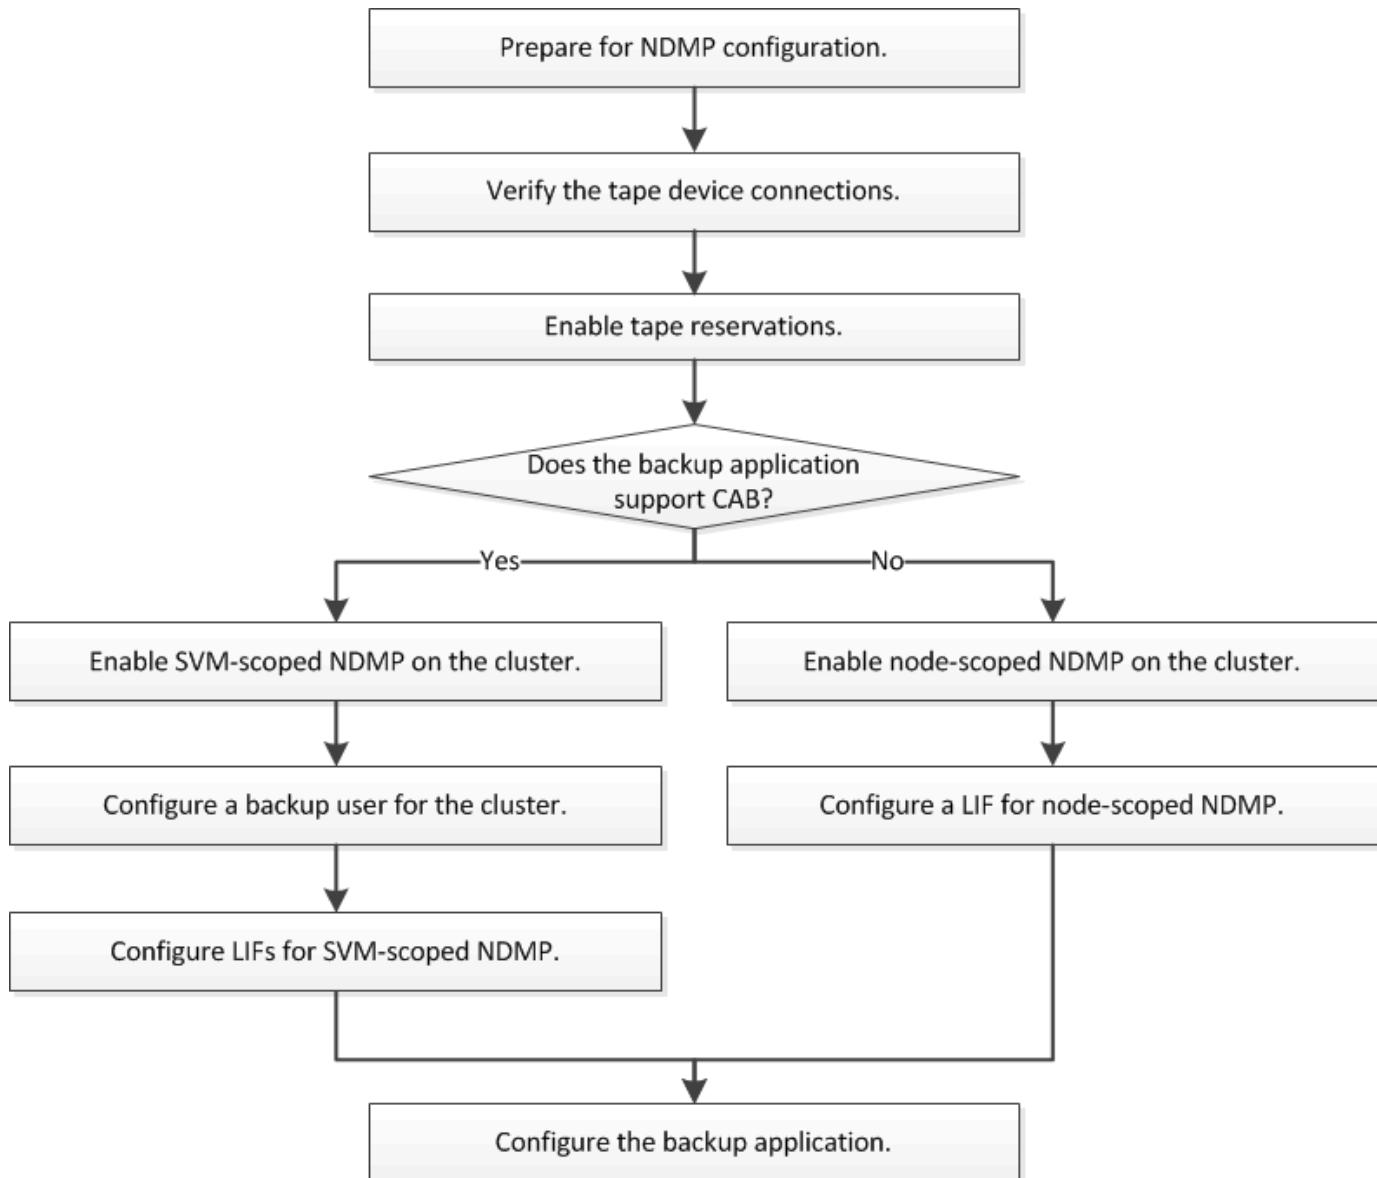

= NDMP configuration workflow

:icons: font

:relative\_path: ./ndmp/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

Setting up tape backup over NDMP involves preparing for NDMP configuration, verifying the tape device connections, enabling tape reservations, configuring NDMP at the SVM or node level, enabling NDMP on the cluster, configuring a backup user, configuring LIFs, and configuring the backup application.

= Prepare for NDMP configuration

:icons: font

:relative\_path: ./ndmp/

Before you configure tape backup access over Network Data Management Protocol (NDMP), you must verify that the planned configuration is supported, verify that your tape drives are listed as qualified drives on each node, verify that all nodes have intercluster LIFs, and identify whether the backup application supports the Cluster Aware Backup (CAB) extension.

## Steps

1. Refer to your backup application provider's compatibility matrix for ONTAP support (NetApp does not qualify third-party backup applications with ONTAP or NDMP).

You should verify that the following NetApp components are compatible:

- The version of ONTAP 9 that is running on the cluster.
- The backup application vendor and version: for example, Veritas NetBackup 8.2 or CommVault.
- The tape devices details, such as the manufacturer, model, and interface of the tape drives: for example, IBM Ultrium 8 or HPe StoreEver Ultrium 30750 LTO-8.
- The platforms of the nodes in the cluster: for example, FAS8700 or A400.

You can find legacy ONTAP compatibility support matrices for backup applications in the [NetApp Interoperability Matrix Tool](#).

1. Verify that your tape drives are listed as qualified drives in each node's built-in tape configuration file:

- a. On the command line-interface, view the built-in tape configuration file by using the `storage tape show-supported-status` command.

```
cluster1::> storage tape show-supported-status

Node: cluster1-1

Tape Drives Is Supported Support Status
----- -----
----- -----
----- -----
Certance Ultrium 2 true Dynamically Qualified
Certance Ultrium 3 true Dynamically Qualified
Digital DLT2000 true Qualified
```

- b. Compare your tape drives to the list of qualified drives in the output.

The names of the tape devices in the output might vary slightly from the names on the device label or in the Interoperability Matrix. For example, Digital DLT2000 can also be known as DLT2k. You can ignore these minor naming differences.

- c. If a device is not listed as qualified in the output even though the device is qualified according to the Interoperability Matrix, download and install an updated configuration file for the device using the instructions on the NetApp Support Site.

## NetApp Downloads: Tape Device Configuration Files

A qualified device might not be listed in the built-in tape configuration file if the tape device was qualified after the node was shipped.

### 2. Verify that every node in the cluster has an intercluster LIF:

- View the intercluster LIFs on the nodes by using the `network interface show -role intercluster` command.

```
cluster1::> network interface show -role intercluster

 Logical Status Network Current
Current Is
Vserver Interface Admin/Oper Address/Mask Node
Port Home

cluster1 IC1 up/up 192.0.2.65/24 cluster1-1
e0a true
```

- If an intercluster LIF does not exist on any node, create an intercluster LIF by using the `network interface create` command.

```
cluster1::> network interface create -vserver cluster1 -lif IC2 -role
intercluster
-home-node cluster1-2 -home-port e0b -address 192.0.2.68 -netmask
255.255.255.0
-status-admin up -failover-policy local-only -firewall-policy
intercluster

cluster1::> network interface show -role intercluster

 Logical Status Network Current
Current Is
Vserver Interface Admin/Oper Address/Mask Node
Port Home

cluster1 IC1 up/up 192.0.2.65/24 cluster1-1
e0a true
cluster1 IC2 up/up 192.0.2.68/24 cluster1-2
e0b true
```

## Network management

3. Identify whether the backup application supports Cluster Aware Backup (CAB) by using the documentation provided with the backup application.

CAB support is a key factor in determining the type of backup you can perform.

= Verify tape device connections

:icons: font

:relative\_path: ./ndmp/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You must ensure that all drives and media changers are visible in ONTAP as devices.

### Steps

1. View information about all drives and media changers by using the `storage tape show` command.

```
cluster1::> storage tape show

Node: cluster1-01
Device ID Device Type Description
Status

sw4:10.11 tape drive HP LTO-3
normal
0b.125L1 media changer HP MSL G3 Series
normal
0d.4 tape drive IBM LTO 5 ULT3580
normal
0d.4L1 media changer IBM 3573-TL
normal
...
...
```

2. If a tape drive is not displayed, troubleshoot the problem.
3. If a media changer is not displayed, view information about media changers by using the `storage tape show-media-changer` command, and then troubleshoot the problem.

```

cluster1::> storage tape show-media-changer

Media Changer: sw4:10.11L1
 Description: PX70-TL
 WWNN: 2:00a:000e11:10b919
 WWPN: 2:00b:000e11:10b919
 Serial Number: 00FRU7800000_LL1

 Errors: -

Paths:
Node Initiator Alias Device State
Status

----- -----
cluster1-01 2b mc0 in-use
normal
...

```

= Enable tape reservations

:icons: font

:relative\_path: ./ndmp/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You must ensure that tape drives are reserved for use by backup applications for NDMP backup operations.

#### About this task

The reservation settings vary in different backup applications, and these settings must match the backup application and the nodes or servers using the same drives. See the vendor documentation of the backup application for the correct reservation settings.

#### Steps

1. Enable reservations by using the options -option-name tape.reservations -option-value persistent command.

The following command enables reservations with the persistent value:

```

cluster1::> options -option-name tape.reservations -option-value
persistent
2 entries were modified.

```

2. Verify that reservations are enabled on all nodes by using the options tape.reservations command, and then review the output.

```
cluster1::> options tape.reservations

cluster1-1
 tape.reservations persistent

cluster1-2
 tape.reservations persistent
2 entries were displayed.
```

= Configure SVM-scoped NDMP

= Enable SVM-scoped NDMP on the cluster

:icons: font  
:relative\_path: ./ndmp/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/../media/

If the DMA supports the Cluster Aware Backup (CAB) extension, you can back up all the volumes hosted across different nodes in a cluster by enabling SVM-scoped NDMP, enabling NDMP service on the cluster (admin SVM), and configuring LIFs for data and control connection.

#### What you'll need

The CAB extension must be supported by the DMA.

#### About this task

Turning off node-scoped NDMP mode enables SVM-scoped NDMP mode on the cluster.

#### Steps

1. Enable SVM-scoped NDMP mode by using the `system services ndmp` command with the `node-scope-mode` parameter.

```
cluster1::> system services ndmp node-scope-mode off
NDMP node-scope-mode is disabled.
```

2. Enable NDMP service on the admin SVM by using the `vserver services ndmp on` command.

```
cluster1::> vserver services ndmp on -vserver cluster1
```

The authentication type is set to `challenge` by default and plaintext authentication is disabled.

For secure communication, you should keep plaintext authentication disabled.

3. Verify that NDMP service is enabled by using the `vserver services ndmp show` command.

```

cluster1::> vserver services ndmp show

Vserver Enabled Authentication type

cluster1 true challenge
vs1 false challenge

```

= Enable a backup user for NDMP authentication

:icons: font

:relative\_path: ./ndmp/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

To authenticate SVM-scoped NDMP from the backup application, there must be an administrative user with sufficient privileges and an NDMP password.

### About this task

You must generate an NDMP password for backup admin users. You can enable backup admin users at the cluster or SVM level, and if necessary, you can create a new user. By default, the users with the following roles can authenticate for NDMP backup:

- Cluster-wide: admin or backup
- Individual SVMs: vsadmin or vsadmin-backup

If you are using an NIS or LDAP user, the user must exist on the respective server. You cannot use an Active Directory user.

### Steps

1. Display the current admin users and permissions:

```
security login show
```

2. If needed, create a new NDMP backup user with the security login create command and the appropriate role for cluster-wide or individual SVM privileges.

You can specify a local backup user name or an NIS or LDAP user name for the `-user-or-group-name` parameter.

The following command creates the backup user `backup_admin1` with the `backup` role for the entire cluster:

```
cluster1::> security login create -user-or-group-name backup_admin1
-application ssh -authmethod password -role backup
```

The following command creates the backup user `vsbackup_admin1` with the `vsadmin-backup` role for an individual SVM:

```
cluster1::> security login create -user-or-group-name vsbackup_admin1
-application ssh -authmethod password -role vsadmin-backup
```

Enter a password for the new user and confirm.

3. Generate a password for the admin SVM by using the `vserver services ndmp generate password` command.

The generated password must be used to authenticate the NDMP connection by the backup application.

```
cluster1::> vserver services ndmp generate-password -vserver cluster1
-user backup_admin1

Vserver: cluster1
User: backup_admin1
Password: qG5CqQHYxw7tE57g
```

= Configure LIFs

```
:icons: font
:relative_path: ./ndmp/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/
```

You must identify the LIFs that will be used for establishing a data connection between the data and tape resources, and for control connection between the admin SVM and the backup application. After identifying the LIFs, you must verify that firewall and failover policies are set for the LIFs, and specify the preferred interface role.

Beginning with ONTAP 9.10.1, firewall policies are deprecated and wholly replaced with LIF service policies. For more information, see [LIFs and service policies in ONTAP 9.6 and later](#).

## Steps

1. Identify the intercluster, cluster-management, and node-management LIFs by using the `network interface show` command with the `-role` parameter.

The following command displays the intercluster LIFs:

```
cluster1::> network interface show -role intercluster

 Logical Status Network Current
Current Is
Vserver Interface Admin/Oper Address/Mask Node
Port Home

cluster1 IC1 up/up 192.0.2.65/24 cluster1-1
e0a true
cluster1 IC2 up/up 192.0.2.68/24 cluster1-2
e0b true
```

The following command displays the cluster-management LIF:

```

cluster1::> network interface show -role cluster-mgmt

 Logical Status Network Current
Current Is
Vserver Interface Admin/Oper Address/Mask Node
Port Home
----- -----
----- -----
cluster1 cluster_mgmt up/up 192.0.2.60/24 cluster1-2
e0M true

```

The following command displays the node-management LIFs:

```

cluster1::> network interface show -role node-mgmt

 Logical Status Network Current
Current Is
Vserver Interface Admin/Oper Address/Mask Node
Port Home
----- -----
----- -----
cluster1 cluster1-1_mgmt1 up/up 192.0.2.69/24 cluster1-1
e0M true
 cluster1-2_mgmt1 up/up 192.0.2.70/24 cluster1-2
e0M true

```

2. Ensure that the firewall policy is enabled for NDMP on the intercluster, cluster-management (cluster-mgmt), and node-management (node-mgmt) LIFs:

- a. Verify that the firewall policy is enabled for NDMP by using the `system services firewall policy show` command.

The following command displays the firewall policy for the cluster-management LIF:

```
cluster1::> system services firewall policy show -policy cluster

Vserver Policy Service Allowed
----- ----- ----- -----
cluster cluster dns 0.0.0.0/0
 http 0.0.0.0/0
 https 0.0.0.0/0
 ** ndmp 0.0.0.0/0**
 ndmps 0.0.0.0/0
 ntp 0.0.0.0/0
 rsh 0.0.0.0/0
 snmp 0.0.0.0/0
 ssh 0.0.0.0/0
 telnet 0.0.0.0/0

10 entries were displayed.
```

The following command displays the firewall policy for the intercluster LIF:

```
cluster1::> system services firewall policy show -policy intercluster

Vserver Policy Service Allowed
----- ----- ----- -----
cluster1 intercluster dns -
 http -
 https -
 ndmp 0.0.0.0/0, ::/0
 ndmps -
 ntp -
 rsh -
 ssh -
 telnet -
```

9 entries were displayed.

The following command displays the firewall policy for the node-management LIF:

```

cluster1::> system services firewall policy show -policy mgmt

Vserver Policy Service Allowed
----- ----- -----
cluster1-1 mgmt dns 0.0.0.0/0, ::/0
 http 0.0.0.0/0, ::/0
 https 0.0.0.0/0, ::/0
 ndmp 0.0.0.0/0, ::/0
 ndmps 0.0.0.0/0, ::/0
 ntp 0.0.0.0/0, ::/0
 rsh -
 snmp 0.0.0.0/0, ::/0
 ssh 0.0.0.0/0, ::/0
 telnet -
10 entries were displayed.

```

- b. If the firewall policy is not enabled, enable the firewall policy by using the `system services firewall policy modify` command with the `-service` parameter.

The following command enables firewall policy for the intercluster LIF:

```

cluster1::> system services firewall policy modify -vserver cluster1
-priority intercluster -service ndmp 0.0.0.0/0

```

3. Ensure that the failover policy is set appropriately for all the LIFs:

- a. Verify that the failover policy for the cluster-management LIF is set to broadcast-domain-wide, and the policy for the intercluster and node-management LIFs is set to local-only by using the `network interface show -failover` command.

The following command displays the failover policy for the cluster-management, intercluster, and node-management LIFs:

```

cluster1::> network interface show -failover

 Logical Home Failover
Failover
Vserver Interface Node:Port Policy
Group

----- cluster cluster1_clus1 cluster1-1:e0a local-only
cluster

Targets: Failover

**cluster1 cluster_mgmt cluster1-1:e0m broadcast-domain-
wide Default** Failover
Targets:

**IC1 cluster1-1:e0a local-only
Default** Failover
Targets:
**IC2 cluster1-1:e0b local-only
Default** Failover
Targets:
**cluster1-1 cluster1-1_mgmt1 cluster1-1:e0m local-only
Default** Failover
Targets:
**cluster1-2 cluster1-2_mgmt1 cluster1-2:e0m local-only
Default** Failover
Targets:

```

- b. If the failover policies are not set appropriately, modify the failover policy by using the `network interface modify` command with the `-failover-policy` parameter.

```

cluster1::> network interface modify -vserver cluster1 -lif IC1
-failover-policy local-only

```

4. Specify the LIFs that are required for data connection by using the `vserver services ndmp modify` command with the `preferred-interface-role` parameter.

```
cluster1::> vserver services ndmp modify -vserver cluster1 -preferred-interface-role intercluster,cluster-mgmt,node-mgmt
```

5. Verify that the preferred interface role is set for the cluster by using the `vserver services ndmp show` command.

```
cluster1::> vserver services ndmp show -vserver cluster1

 Vserver: cluster1
 NDMP Version: 4

Preferred Interface Role: intercluster, cluster-mgmt, node-mgmt
```

= Configure node-scoped NDMP

= Enable node-scoped NDMP on the cluster

:icons: font

:relative\_path: ./ndmp/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can back up volumes hosted on a single node by enabling node-scoped NDMP, enabling the NDMP service, and configuring a LIF for data and control connection. This can be done for all nodes of the cluster.

Node-scoped NDMP is deprecated in ONTAP 9.

#### About this task

When using NDMP in node-scope mode, authentication must be configured on a per-node basis. For more information, see the [Knowledge Base article "How to configure NDMP authentication in the 'node-scope' mode"](#).

#### Steps

1. Enable node-scoped NDMP mode by using the `system services ndmp` command with the `node-scope-mode` parameter.

```
cluster1::> system services ndmp node-scope-mode on
NDMP node-scope-mode is enabled.
```

2. Enable NDMP service on all nodes in the cluster by using the `system services ndmp on` command.

Using the wildcard “\*” enables NDMP service on all nodes at the same time.

You must specify a password for authentication of the NDMP connection by the backup application.

```
cluster1::> system services ndmp on -node *
Please enter password:
Confirm password:
2 entries were modified.
```

3. Disable the `-clear-text` option for secure communication of the NDMP password by using the `system services ndmp modify` command.

Using the wildcard “\*” disables the `-clear-text` option on all nodes at the same time.

```
cluster1::> system services ndmp modify -node * -clear-text false
2 entries were modified.
```

4. Verify that NDMP service is enabled and the `-clear-text` option is disabled by using the `system services ndmp show` command.

```
cluster1::> system services ndmp show
Node Enabled Clear text User Id

cluster1-1 true false root
cluster1-2 true false root
2 entries were displayed.
```

= Configure a LIF

:icons: font

:relative\_path: ./ndmp/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

You must identify a LIF that will be used for establishing a data connection and control connection between the node and the backup application. After identifying the LIF, you must verify that firewall and failover policies are set for the LIF.

Beginning with ONTAP 9.10.1, firewall policies are deprecated and wholly replaced with LIF service policies. For more information, see [Configure firewall policies for LIFs](#).

## Steps

1. Identify the intercluster LIF hosted on the nodes by using the `network interface show` command with the `-role` parameter.

```

cluster1::> network interface show -role intercluster

 Logical Status Network Current
Current Is
Vserver Interface Admin/Oper Address/Mask Node Port
Home

----- ----
cluster1 IC1 up/up 192.0.2.65/24 cluster1-1 e0a
true
cluster1 IC2 up/up 192.0.2.68/24 cluster1-2 e0b
true

```

2. Ensure that the firewall policy is enabled for NDMP on the intercluster LIFs:

- a. Verify that the firewall policy is enabled for NDMP by using the `system services firewall policy show` command.

The following command displays the firewall policy for the intercluster LIF:

```

cluster1::> system services firewall policy show -policy intercluster

Vserver Policy Service Allowed

cluster1 intercluster dns -
 http -
 https -
 ndmp 0.0.0.0/0, ::/0
 ndmps -
 ntp -
 rsh -
 ssh -
 telnet -
9 entries were displayed.

```

- b. If the firewall policy is not enabled, enable the firewall policy by using the `system services firewall policy modify` command with the `-service` parameter.

The following command enables firewall policy for the intercluster LIF:

```

cluster1::> system services firewall policy modify -vserver cluster1
-priority intercluster -service ndmp 0.0.0.0/0

```

3. Ensure that the failover policy is set appropriately for the intercluster LIFs:

- a. Verify that the failover policy for the intercluster LIFs is set to local-only by using the network interface show -failover command.

```
cluster1::> network interface show -failover
 Logical Home Failover Failover
Vserver Interface Node:Port Policy Group

cluster1 **IC1 cluster1-1:e0a local-only
Default** Failover Targets:

 **IC2 cluster1-2:e0b local-only
Default** Failover Targets:

cluster1-1 cluster1-1_mgmt1 cluster1-1:e0m local-only Default
 Failover Targets:

```

- b. If the failover policy is not set appropriately, modify the failover policy by using the network interface modify command with the -failover-policy parameter.

```
cluster1::> network interface modify -vserver cluster1 -lif IC1
-failover-policy local-only
```

= Configure the backup application

:icons: font

:relative\_path: ./ndmp/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

After the cluster is configured for NDMP access, you must gather information from the cluster configuration and then configure the rest of the backup process in the backup application.

## Steps

1. Gather the following information that you configured earlier in ONTAP:
  - The user name and password that the backup application requires to create the NDMP connection
  - The IP addresses of the intercluster LIFs that the backup application requires to connect to the cluster
2. In ONTAP, display the aliases that ONTAP assigned to each device by using the storage tape alias show command.

The aliases are often useful in configuring the backup application.

```
cluster1::> storage tape show -alias
```

```
Device ID: 2a.0
Device Type: tape drive
Description: Hewlett-Packard LTO-5
```

| Node               | Alias | Mapping        |
|--------------------|-------|----------------|
| stsw-3220-4a-4b-02 | st2   | SN[HU19497WVR] |
| ...                |       |                |

3. In the backup application, configure the rest of the backup process by using the backup application's documentation.

#### After you finish

If a data mobility event occurs, such as a volume move or LIF migration, you must be prepared to reinitialize any interrupted backup operations.

= Replication between NetApp Element software and ONTAP

= Replication between NetApp Element software and ONTAP overview

:icons: font

:relative\_path: ./element-replication/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can ensure business continuity on an Element system by using SnapMirror to replicate Snapshot copies of an Element volume to an ONTAP destination. In the event of a disaster at the Element site, you can serve data to clients from the ONTAP system, and then reactivate the Element system when service is restored.

Beginning with ONTAP 9.4, you can replicate Snapshot copies of a LUN created on an ONTAP node back to an Element system. You might have created a LUN during an outage at the Element site, or you might be using a LUN to migrate data from ONTAP to Element software.

You should work with Element to ONTAP backup if the following apply:

- You want to use best practices, not explore every available option.
- You want to use the ONTAP command-line interface (CLI), not System Manager or an automated scripting tool.
- You are using iSCSI to serve data to clients.

If you require additional configuration or conceptual information, see the following documentation:

- Element configuration

[NetApp Element software documentation](#)

- SnapMirror concepts and configuration

[Data protection overview](#)

## == About replication between Element and ONTAP

Beginning with ONTAP 9.3, you can use SnapMirror to replicate Snapshot copies of an Element volume to an ONTAP destination. In the event of a disaster at the Element site, you can serve data to clients from the ONTAP system, then reactivate the Element source volume when service is restored.

Beginning with ONTAP 9.4, you can replicate Snapshot copies of a LUN created on an ONTAP node back to an Element system. You might have created a LUN during an outage at the Element site, or you might be using a LUN to migrate data from ONTAP to Element software.

## == Types of data protection relationship

SnapMirror offers two types of data protection relationship. For each type, SnapMirror creates a Snapshot copy of the Element source volume before initializing or updating the relationship:

- In a *disaster recovery (DR)* data protection relationship, the destination volume contains only the Snapshot copy created by SnapMirror, from which you can continue to serve data in the event of a catastrophe at the primary site.
- In a *long-term retention* data protection relationship, the destination volume contains point-in-time Snapshot copies created by Element software, as well as the Snapshot copy created by SnapMirror. You might want to retain monthly Snapshot copies created over a 20-year span, for example.

## == Default policies

The first time you invoke SnapMirror, it performs a *baseline transfer* from the source volume to the destination volume. The *SnapMirror policy* defines the contents of the baseline and any updates.

You can use a default or custom policy when you create a data protection relationship. The *policy type* determines which Snapshot copies to include and how many copies to retain.

The table below shows the default policies. Use the `MirrorLatest` policy to create a traditional DR relationship. Use the `MirrorAndVault` or `Unified7year` policy to create a unified replication relationship, in which DR and long-term retention are configured on the same destination volume.

| Policy                      | Policy Type               | Update behavior                                                                                                                                                                        |
|-----------------------------|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>MirrorLatest</code>   | <code>async-mirror</code> | Transfer the Snapshot copy created by SnapMirror.                                                                                                                                      |
| <code>MirrorAndVault</code> | <code>mirror-vault</code> | Transfer the Snapshot copy created by SnapMirror and any less recent Snapshot copies made since the last update, provided they have SnapMirror labels “daily” or “weekly”.             |
| <code>Unified7year</code>   | <code>mirror-vault</code> | Transfer the Snapshot copy created by SnapMirror and any less recent Snapshot copies made since the last update, provided they have SnapMirror labels “daily”, “weekly”, or “monthly”. |

For complete background information on SnapMirror policies, including guidance on which policy to use, see [Data Protection](#).

## == Understanding SnapMirror labels

Every policy with the “mirror-vault” policy type must have a rule that specifies which Snapshot copies to replicate. The rule “daily”, for example, indicates that only Snapshot copies assigned the SnapMirror label “daily” should be replicated. You assign the SnapMirror label when you configure Element Snapshot copies.

#### ==== Replication from an Element source cluster to an ONTAP destination cluster

You can use SnapMirror to replicate Snapshot copies of an Element volume to an ONTAP destination system. In the event of a disaster at the Element site, you can serve data to clients from the ONTAP system, then reactivate the Element source volume when service is restored.

An Element volume is roughly equivalent to an ONTAP LUN. SnapMirror creates a LUN with the name of the Element volume when a data protection relationship between Element software and ONTAP is initialized. SnapMirror replicates data to an existing LUN if the LUN meets the requirements for Element to ONTAP replication.

Replication rules are as follows:

- An ONTAP volume can contain data from one Element volume only.
- You cannot replicate data from an ONTAP volume to multiple Element volumes.

#### ==== Replication from an ONTAP source cluster to an Element destination cluster

Beginning with ONTAP 9.4, you can replicate Snapshot copies of a LUN created on an ONTAP system back to an Element volume:

- If a SnapMirror relationship already exists between an Element source and an ONTAP destination, a LUN created while you are serving data from the destination is automatically replicated when the source is reactivated.
- Otherwise, you must create and initialize a SnapMirror relationship between the ONTAP source cluster and the Element destination cluster.

Replication rules are as follows:

- The replication relationship must have a policy of type “async-mirror”. Policies of type “mirror-vault” are not supported.
- Only iSCSI LUNs are supported.
- You cannot replicate more than one LUN from an ONTAP volume to an Element volume.
- You cannot replicate a LUN from an ONTAP volume to multiple Element volumes.

#### ==== Prerequisites

You must have completed the following tasks before configuring a data protection relationship between Element and ONTAP:

- The Element cluster must be running NetApp Element software version 10.1 or later.
- The ONTAP cluster must be running ONTAP 9.3 or later.
- SnapMirror must have been licensed on the ONTAP cluster.
- You must have configured volumes on the Element and ONTAP clusters that are large enough to handle anticipated data transfers.

- If you are using the “mirror-vault” policy type, a SnapMirror label must have been configured for the Element Snapshot copies to be replicated.

You can perform this task in the Element software web UI only. For more information, see the [NetApp Element software documentation](#)

- You must have ensured that port 5010 is available.
- If you foresee that you might need to move a destination volume, you must have ensured that full-mesh connectivity exists between the source and destination. Every node on the Element source cluster must be able to communicate with every node on the ONTAP destination cluster.

### ==== Support details

The following table shows support details for Element to ONTAP backup.

| Resource or feature | Support details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SnapMirror          | <ul style="list-style-type: none"> <li>• The SnapMirror restore feature is not supported.</li> <li>• The <code>MirrorAllSnapshots</code> and <code>XDPDefault</code> policies are not supported.</li> <li>• The “vault” policy type is not supported.</li> <li>• The system-defined rule “all_source_snapshots” is not supported.</li> <li>• The “mirror-vault” policy type is supported only for replication from Element software to ONTAP. Use “async-mirror” for replication from ONTAP to Element software.</li> <li>• The <code>-schedule</code> and <code>-prefix</code> options for <code>snapmirror policy add-rule</code> are not supported.</li> <li>• The <code>-preserve</code> and <code>-quick-resync</code> options for <code>snapmirror resync</code> are not supported.</li> <li>• Storage efficiency is not preserved.</li> <li>• Fan-out and cascade data protection deployments are not supported.</li> </ul> |

| SVM DR       | ONTAP volumes in an SVM DR configuration are not supported.                                                                                                                                                                                       |
| MetroCluster | ONTAP volumes in a MetroCluster configuration are not supported.                                                                                                                                                                                  |

= Workflow for replication between Element and ONTAP

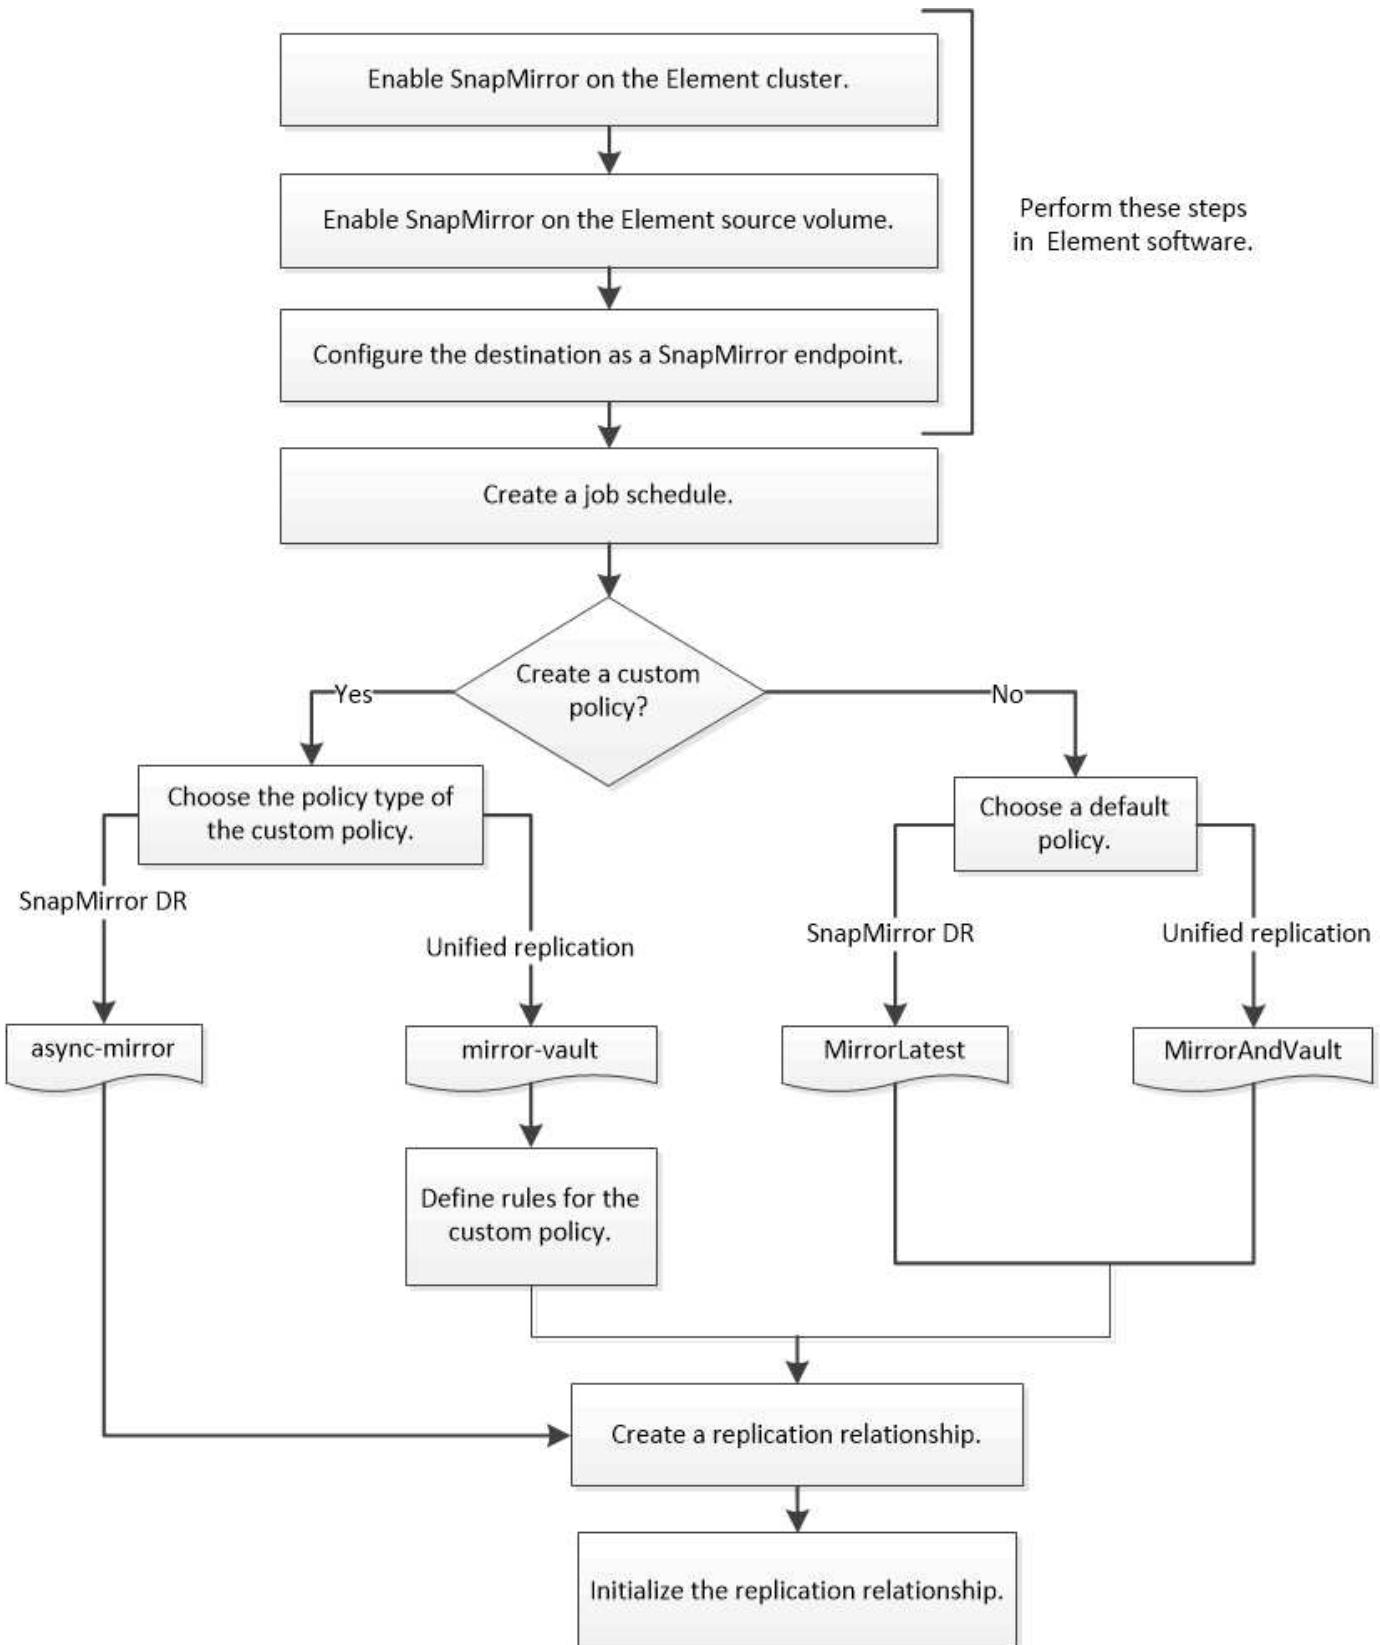

:icons: font

:relative\_path: ./element-replication/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..../media/

Whether you are replicating data from Element to ONTAP or from ONTAP to Element, you need to configure a job schedule, specify a policy, and create and initialize the relationship. You can use a default or custom policy.

The workflow assumes that you have completed the prerequisite tasks listed in [Prerequisites](#). For complete background information on SnapMirror policies, including guidance on which policy to use, see [Data protection](#).

= Enable SnapMirror in Element software

= Enable SnapMirror on the Element cluster

:icons: font

:relative\_path: ./element-replication/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

You must enable SnapMirror on the Element cluster before you can create a replication relationship. You can perform this task in the Element software web UI only.

#### Before you begin

- The Element cluster must be running NetApp Element software version 10.1 or later.
- SnapMirror can only be enabled for Element clusters used with NetApp ONTAP volumes.

#### About this task

The Element system comes with SnapMirror disabled by default. SnapMirror is not automatically enabled as part of a new installation or upgrade.

Once enabled, SnapMirror cannot be disabled. You can only disable the SnapMirror feature and restore the default settings by returning the cluster to the factory image.

#### Steps

1. Click **Clusters > Settings**.
2. Find the cluster-specific settings for SnapMirror.
3. Click **Enable SnapMirror**.

= Enable SnapMirror on the Element source volume

:icons: font

:relative\_path: ./element-replication/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You must enable SnapMirror on the Element source volume before you can create a replication relationship. You can perform this task in the Element software web UI only.

#### Before you begin

- You must have enabled SnapMirror on the Element cluster.
- The volume block size must be 512 bytes.
- The volume must not be participating in Element remote replication.
- The volume access type must not be “Replication Target”.

#### About this task

The procedure below assumes the volume already exists. You can also enable SnapMirror when you create or clone a volume.

#### Steps

1. Click **Management > Volumes**.
2. Click the button for the volume.
3. In the drop-down menu, select **Edit**.
4. In the **Edit Volume** dialog, select **Enable SnapMirror**.
5. Click **Save Changes**.

= Create a SnapMirror endpoint

:icons: font

:relative\_path: ./element-replication/

```
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/
```

You must create a SnapMirror endpoint before you can create a replication relationship. You can perform this task in the Element software web UI only.

### Before you begin

You must have enabled SnapMirror on the Element cluster.

### Steps

1. Click **Data Protection > SnapMirror Endpoints**.
2. Click **Create Endpoint**.
3. In the **Create a New Endpoint** dialog, enter the ONTAP cluster management IP address.
4. Enter the user ID and password of the ONTAP cluster administrator.
5. Click **Create Endpoint**.

= Configure a replication relationship

= Create a replication job schedule

:icons: font

:relative\_path: ./element-replication/

```
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/
```

Whether you are replicating data from Element to ONTAP or from ONTAP to Element, you need to configure a job schedule, specify a policy, and create and initialize the relationship. You can use a default or custom policy.

You can use the `job schedule cron create` command to create a replication job schedule. The job schedule determines when SnapMirror automatically updates the data protection relationship to which the schedule is assigned.

### About this task

You assign a job schedule when you create a data protection relationship. If you do not assign a job schedule, you must update the relationship manually.

### Step

1. Create a job schedule:

```
job schedule cron create -name job_name -month month -dayofweek day_of_week
-day day_of_month -hour hour -minute minute
```

For `-month`, `-dayofweek`, and `-hour`, you can specify `all` to run the job every month, day of the week, and hour, respectively.

Beginning with ONTAP 9.10.1, you can include the Vserver for your job schedule:

```
job schedule cron create -name job_name -vserver Vserver_name -month month
-dayofweek day_of_week -day day_of_month -hour hour -minute minute
```

The following example creates a job schedule named `my_weekly` that runs on Saturdays at 3:00 a.m.:

```
cluster_dst::> job schedule cron create -name my_weekly -dayofweek
"Saturday" -hour 3 -minute 0
```

= Customize a replication policy

= Create a custom replication policy

:icons: font

:relative\_path: ./element-replication/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can use a default or custom policy when you create a replication relationship. For a custom unified replication policy, you must define one or more *rules* that determine which Snapshot copies are transferred during initialization and update.

You can create a custom replication policy if the default policy for a relationship is not suitable. You might want to compress data in a network transfer, for example, or modify the number of attempts SnapMirror makes to transfer Snapshot copies.

### About this task

The *policy type* of the replication policy determines the type of relationship it supports. The table below shows the available policy types.

| Policy type  | Relationship type   |
|--------------|---------------------|
| async-mirror | SnapMirror DR       |
| mirror-vault | Unified replication |

### Step

1. Create a custom replication policy:

```
snapmirror policy create -vserver SVM -policy policy -type async-
mirror|mirror-vault -comment comment -tries transfer_tries -transfer-priority
low|normal -is-network-compression-enabled true|false
```

For complete command syntax, see the man page.

Beginning with ONTAP 9.5, you can specify the schedule for creating a common Snapshot copy schedule for SnapMirror Synchronous relationships by using the *-common-snapshot-schedule* parameter. By default, the common Snapshot copy schedule for SnapMirror Synchronous relationships is one hour. You can specify a value from 30 minutes to two hours for the Snapshot copy schedule for SnapMirror Synchronous relationships.

The following example creates a custom replication policy for SnapMirror DR that enables network compression for data transfers:

```
cluster_dst::> snapmirror policy create -vserver svml -policy
DR_compressed -type async-mirror -comment "DR with network compression
enabled" -is-network-compression-enabled true
```

The following example creates a custom replication policy for unified replication:

```
cluster_dst::> snapmirror policy create -vserver svml -policy my_unified
-type mirror-vault
```

### After you finish

For “mirror-vault” policy types, you must define rules that determine which Snapshot copies are transferred during initialization and update.

Use the `snapmirror policy show` command to verify that the SnapMirror policy was created. For complete command syntax, see the man page.

```
= Define a rule for a policy
:icons: font
:relative_path: ./element-replication/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/
```

For custom policies with the “mirror-vault” policy type, you must define at least one rule that determines which Snapshot copies are transferred during initialization and update. You can also define rules for default policies with the “mirror-vault” policy type.

### About this task

Every policy with the “mirror-vault” policy type must have a rule that specifies which Snapshot copies to replicate. The rule “bi-monthly”, for example, indicates that only Snapshot copies assigned the SnapMirror label “bi-monthly” should be replicated. You assign the SnapMirror label when you configure Element Snapshot copies.

Each policy type is associated with one or more system-defined rules. These rules are automatically assigned to a policy when you specify its policy type. The table below shows the system-defined rules.

| System-defined rule | Used in policy types       | Result                                                                                                            |
|---------------------|----------------------------|-------------------------------------------------------------------------------------------------------------------|
| sm_created          | async-mirror, mirror-vault | A Snapshot copy created by SnapMirror is transferred on initialization and update.                                |
| daily               | mirror-vault               | New Snapshot copies on the source with the SnapMirror label “daily” are transferred on initialization and update. |

|         |              |                                                                                                                     |
|---------|--------------|---------------------------------------------------------------------------------------------------------------------|
| weekly  | mirror-vault | New Snapshot copies on the source with the SnapMirror label "weekly" are transferred on initialization and update.  |
| monthly | mirror-vault | New Snapshot copies on the source with the SnapMirror label "monthly" are transferred on initialization and update. |

You can specify additional rules as needed, for default or custom policies. For example:

- For the default MirrorAndVault policy, you might create a rule called "bi-monthly" to match Snapshot copies on the source with the "bi-monthly" SnapMirror label.
- For a custom policy with the "mirror-vault" policy type, you might create a rule called "bi-weekly" to match Snapshot copies on the source with the "bi-weekly" SnapMirror label.

### Step

1. Define a rule for a policy:

```
snapmirror policy add-rule -vserver SVM -policy policy_for_rule -snapmirror
-label snapmirror-label -keep retention_count
```

For complete command syntax, see the man page.

The following example adds a rule with the SnapMirror label `bi-monthly` to the default `MirrorAndVault` policy:

```
cluster_dst::> snapmirror policy add-rule -vserver svml -policy
MirrorAndVault -snapmirror-label bi-monthly -keep 6
```

The following example adds a rule with the SnapMirror label `bi-weekly` to the custom `my_snapvault` policy:

```
cluster_dst::> snapmirror policy add-rule -vserver svml -policy
my_snapvault -snapmirror-label bi-weekly -keep 26
```

The following example adds a rule with the SnapMirror label `app_consistent` to the custom `Sync` policy:

```
cluster_dst::> snapmirror policy add-rule -vserver svml -policy Sync
-snapmirror-label app_consistent -keep 1
```

You can then replicate Snapshot copies from the source cluster that match this SnapMirror label:

```
cluster_src::> snapshot create -vserver vs1 -volume vol1 -snapshot
snapshot1 -snapmirror-label app_consistent
```

= Create a replication relationship

= Create a relationship from an Element source to an ONTAP destination

:icons: font

:relative\_path: ./element-replication/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

The relationship between the source volume in primary storage and the destination volume in secondary storage is called a *data protection relationship*. You can use the `snapmirror create` command to create a data protection relationship from an Element source to an ONTAP destination, or from an ONTAP source to an Element destination.

You can use SnapMirror to replicate Snapshot copies of an Element volume to an ONTAP destination system. In the event of a disaster at the Element site, you can serve data to clients from the ONTAP system, then reactivate the Element source volume when service is restored.

### Before you begin

- The Element node containing the volume to be replicated must have been made accessible to ONTAP.
- The Element volume must have been enabled for SnapMirror replication.
- If you are using the “mirror-vault” policy type, a SnapMirror label must have been configured for the Element Snapshot copies to be replicated.

You can perform this task in the Element software web UI only. For more information, see the [Element documentation](#).

### About this task

You must specify the Element source path in the form `hostip:/lun/name`, where “lun” is the actual string “lun” and name is the name of the Element volume.

An Element volume is roughly equivalent to an ONTAP LUN. SnapMirror creates a LUN with the name of the Element volume when a data protection relationship between Element software and ONTAP is initialized. SnapMirror replicates data to an existing LUN if the LUN meets the requirements for replicating from Element software to ONTAP.

Replication rules are as follows:

- An ONTAP volume can contain data from one Element volume only.
- You cannot replicate data from an ONTAP volume to multiple Element volumes.

In ONTAP 9.3 and earlier, a destination volume can contain up to 251 Snapshot copies. In ONTAP 9.4 and later, a destination volume can contain up to 1019 Snapshot copies.

### Step

1. From the destination cluster, create a replication relationship from an Element source to an ONTAP

destination:

```
snapmirror create -source-path hostip:/lun/name -destination-path SVM:volume
|cluster://SVM/volume -type XDP -schedule schedule -policy policy
```

For complete command syntax, see the man page.

The following example creates a SnapMirror DR relationship using the default `MirrorLatest` policy:

```
cluster_dst:> snapmirror create -source-path 10.0.0.11:/lun/0005
-destination-path svm_backup:volA_dst -type XDP -schedule my_daily
-policy MirrorLatest
```

The following example creates a unified replication relationship using the default `MirrorAndVault` policy:

```
cluster_dst:> snapmirror create -source-path 10.0.0.11:/lun/0005
-destination-path svm_backup:volA_dst -type XDP -schedule my_daily
-policy MirrorAndVault
```

The following example creates a unified replication relationship using the `Unified7year` policy:

```
cluster_dst:> snapmirror create -source-path 10.0.0.11:/lun/0005
-destination-path svm_backup:volA_dst -type XDP -schedule my_daily
-policy Unified7year
```

The following example creates a unified replication relationship using the custom `my_unified` policy:

```
cluster_dst:> snapmirror create -source-path 10.0.0.11:/lun/0005
-destination-path svm_backup:volA_dst -type XDP -schedule my_daily
-policy my_unified
```

## After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created. For complete command syntax, see the man page.

= Create a relationship from an ONTAP source to an Element destination  
:icons: font  
:relative\_path: ./element-replication/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

Beginning with ONTAP 9.4, you can use SnapMirror to replicate Snapshot copies of a LUN created on an ONTAP source back to an Element destination. You might be using the LUN to migrate data from ONTAP to Element software.

## Before you begin

- The Element destination node must have been made accessible to ONTAP.
- The Element volume must have been enabled for SnapMirror replication.

## About this task

You must specify the Element destination path in the form `hostip:/lun/name`, where “lun” is the actual string “lun” and name is the name of the Element volume.

Replication rules are as follows:

- The replication relationship must have a policy of type “async-mirror”.
  - You can use a default or custom policy.
- Only iSCSI LUNs are supported.
- You cannot replicate more than one LUN from an ONTAP volume to an Element volume.
- You cannot replicate a LUN from an ONTAP volume to multiple Element volumes.

## Step

1. Create a replication relationship from an ONTAP source to an Element destination:

```
snapmirror create -source-path SVM:volume|cluster://SVM/volume -destination-path hostip:/lun/name -type XDP -schedule schedule -policy policy
```

For complete command syntax, see the man page.

The following example creates a SnapMirror DR relationship using the default `MirrorLatest` policy:

```
cluster_dst::> snapmirror create -source-path svm_1:volA_dst
-destination-path 10.0.0.11:/lun/0005 -type XDP -schedule my_daily
-policy MirrorLatest
```

The following example creates a SnapMirror DR relationship using the custom `my_mirror` policy:

```
cluster_dst::> snapmirror create -source-path svm_1:volA_dst
-destination-path 10.0.0.11:/lun/0005 -type XDP -schedule my_daily
-policy my_mirror
```

## After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created. For complete command syntax, see the man page.

= Initialize a replication relationship  
:icons: font  
:relative\_path: ./element-replication/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

For all relationship types, initialization performs a *baseline transfer*: it makes a Snapshot copy of the source volume, then transfers that copy and all the data blocks it references to the destination volume.

### Before you begin

- The Element node containing the volume to be replicated must have been made accessible to ONTAP.
- The Element volume must have been enabled for SnapMirror replication.
- If you are using the “mirror-vault” policy type, a SnapMirror label must have been configured for the Element Snapshot copies to be replicated.

### About this task

You must specify the Element source path in the form *hostip*:/lun/*name*, where “lun” is the actual string “lun” and *name* is the name of the Element volume.

Initialization can be time-consuming. You might want to run the baseline transfer in off-peak hours.

If initialization of a relationship from an ONTAP source to an Element destination fails for any reason, it will continue to fail even after you have corrected the problem (an invalid LUN name, for example). The workaround is as follows:

1. Delete the relationship.
2. Delete the Element destination volume.
3. Create a new Element destination volume.
4. Create and initialize a new relationship from the ONTAP source to the Element destination volume.

### Step

1. Initialize a replication relationship:

```
snapmirror initialize -source-path hostip:/lun/name -destination-path
SVM:volume|cluster://SVM/volume
```

For complete command syntax, see the man page.

The following example initializes the relationship between the source volume 0005 at IP address 10.0.0.11 and the destination volume volA\_dst on svm\_backup:

```
cluster_dst:> snapmirror initialize -source-path 10.0.0.11:/lun/0005
-destination-path svm_backup:volA_dst
```

= Serve data from a SnapMirror DR destination volume

= Make the destination volume writeable

:icons: font

:relative\_path: ./element-replication/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

When disaster disables the primary site for a SnapMirror DR relationship, you can serve

data from the destination volume with minimal disruption. You can reactivate the source volume when service is restored at the primary site.

You need to make the destination volume writeable before you can serve data from the volume to clients. You can use the `snapmirror quiesce` command to stop scheduled transfers to the destination, the `snapmirror abort` command to stop ongoing transfers, and the `snapmirror break` command to make the destination writeable.

## About this task

You must specify the Element source path in the form `hostip:/lun/name`, where “lun” is the actual string “lun” and name is the name of the Element volume.

## Steps

1. Stop scheduled transfers to the destination:

```
snapmirror quiesce -source-path hostip:/lun/name -destination-path SVM:volume
|cluster://SVM/volume
```

For complete command syntax, see the man page.

The following example stops scheduled transfers between the source volume 0005 at IP address 10.0.0.11 and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror quiesce -source-path 10.0.0.11:/lun/0005
-destination-path svm_backup:volA_dst
```

2. Stop ongoing transfers to the destination:

```
snapmirror abort -source-path hostip:/lun/name -destination-path SVM:volume
|cluster://SVM/volume
```

For complete command syntax, see the man page.

The following example stops ongoing transfers between the source volume 0005 at IP address 10.0.0.11 and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror abort -source-path 10.0.0.11:/lun/0005
-destination-path svm_backup:volA_dst
```

3. Break the SnapMirror DR relationship:

```
snapmirror break -source-path hostip:/lun/name -destination-path SVM:volume
|cluster://SVM/volume
```

For complete command syntax, see the man page.

The following example breaks the relationship between the source volume 0005 at IP address 10.0.0.11 and the destination volume `volA_dst` on `svm_backup` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror break -source-path 10.0.0.11:/lun/0005
-destination-path svm_backup:volA_dst
```

= Configure the destination volume for data access  
:icons: font  
:relative\_path: ./element-replication/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

After making the destination volume writeable, you must configure the volume for data access. SAN hosts can access the data from the destination volume until the source volume is reactivated.

1. Map the Element LUN to the appropriate initiator group.
2. Create iSCSI sessions from the SAN host initiators to the SAN LIFs.
3. On the SAN client, perform a storage re-scan to detect the connected LUN.

= Reactivate the original source volume  
:icons: font  
:relative\_path: ./element-replication/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can reestablish the original data protection relationship between the source and destination volumes when you no longer need to serve data from the destination.

### About this task

The procedure below assumes that the baseline in the original source volume is intact. If the baseline is not intact, you must create and initialize the relationship between the volume you are serving data from and the original source volume before performing the procedure.

You must specify the Element source path in the form *hostip*:/lun/*name*, where “lun” is the actual string “lun” and *name* is the name of the Element volume.

Beginning with ONTAP 9.4, Snapshot copies of a LUN created while you are serving data from the ONTAP destination are automatically replicated when the Element source is reactivated.

Replication rules are as follows:

- Only iSCSI LUNs are supported.
- You cannot replicate more than one LUN from an ONTAP volume to an Element volume.
- You cannot replicate a LUN from an ONTAP volume to multiple Element volumes.

### Steps

1. Delete the original data protection relationship:

```
snapmirror delete -source-path SVM:volume|cluster://SVM/volume -destination
-path hostip:/lun/name -policy policy
```

For complete command syntax, see the man page.

The following example deletes the relationship between the original source volume, 0005 at IP address 10.0.0.11, and the volume you are serving data from, `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror delete -source-path 10.0.0.11:/lun/0005
-policy MirrorLatest -destination-path svm_backup:volA_dst
```

## 2. Reverse the original data protection relationship:

```
snapmirror resync -source-path SVM:volume|cluster://SVM/volume -destination
-path hostip:/lun/name -policy policy
```

For complete command syntax, see the man page.

Although `resync` does not require a baseline transfer, it can be time-consuming. You might want to run the `resync` in off-peak hours.

The following example reverses the relationship between the original source volume, 0005 at IP address 10.0.0.11, and the volume you are serving data from, `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror resync -source-path svm_backup:volA_dst
-destination-path 10.0.0.11:/lun/0005 -policy MirrorLatest
```

## 3. Update the reversed relationship:

```
snapmirror update -source-path SVM:volume|cluster://SVM/volume -destination
-path hostip:/lun/name
```

For complete command syntax, see the man page.

The command fails if a common Snapshot copy does not exist on the source and destination. Use `snapmirror initialize` to re-initialize the relationship.

The following example updates the relationship between the volume you are serving data from, `volA_dst` on `svm_backup`, and the original source volume, 0005 at IP address 10.0.0.11:

```
cluster_dst::> snapmirror update -source-path svm_backup:volA_dst
-destination-path 10.0.0.11:/lun/0005
```

## 4. Stop scheduled transfers for the reversed relationship:

```
snapmirror quiesce -source-path SVM:volume|cluster://SVM/volume -destination
-path hostip:/lun/name
```

For complete command syntax, see the man page.

The following example stops scheduled transfers between the volume you are serving data from, `volA_dst` on `svm_backup`, and the original source volume, 0005 at IP address 10.0.0.11:

```
cluster_dst::> snapmirror quiesce -source-path svm_backup:volA_dst
-destination-path 10.0.0.11:/lun/0005
```

5. Stop ongoing transfers for the reversed relationship:

```
snapmirror abort -source-path SVM:volume|cluster://SVM/volume -destination
-path hostip:/lun/name
```

For complete command syntax, see the man page.

The following example stops ongoing transfers between the volume you are serving data from, volA\_dst on svm\_backup, and the original source volume, 0005 at IP address 10.0.0.11:

```
cluster_dst::> snapmirror abort -source-path svm_backup:volA_dst
-destination-path 10.0.0.11:/lun/0005
```

6. Break the reversed relationship:

```
snapmirror break -source-path SVM:volume|cluster://SVM/volume -destination
-path hostip:/lun/name
```

For complete command syntax, see the man page.

The following example breaks the relationship between the volume you are serving data from, volA\_dst on svm\_backup, and the original source volume, 0005 at IP address 10.0.0.11:

```
cluster_dst::> snapmirror break -source-path svm_backup:volA_dst
-destination-path 10.0.0.11:/lun/0005
```

7. Delete the reversed data protection relationship:

```
snapmirror delete -source-path SVM:volume|cluster://SVM/volume -destination
-path hostip:/lun/name -policy policy
```

For complete command syntax, see the man page.

The following example deletes the reversed relationship between the original source volume, 0005 at IP address 10.0.0.11, and the volume you are serving data from, volA\_dst on svm\_backup:

```
cluster_src::> snapmirror delete -source-path svm_backup:volA_dst
-destination-path 10.0.0.11:/lun/0005 -policy MirrorLatest
```

8. Reestablish the original data protection relationship:

```
snapmirror resync -source-path hostip:/lun/name -destination-path
SVM:volume|cluster://SVM/volume
```

For complete command syntax, see the man page.

The following example reestablishes the relationship between the original source volume, 0005 at IP address 10.0.0.11, and the original destination volume, `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror resync -source-path 10.0.0.11:/lun/0005
-destination-path svm_backup:volA_dst
```

## After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created. For complete command syntax, see the man page.

= Update a replication relationship manually

:icons: font

:relative\_path: ./element-replication/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You might need to update a replication relationship manually if an update fails because of a network error.

## About this task

You must specify the Element source path in the form `hostip:/lun/name`, where “lun” is the actual string “lun” and name is the name of the Element volume.

## Steps

1. Update a replication relationship manually:

```
snapmirror update -source-path hostip:/lun/name -destination-path SVM:volume
| cluster://SVM/volume
```

For complete command syntax, see the man page.

The command fails if a common Snapshot copy does not exist on the source and destination. Use `snapmirror initialize` to re-initialize the relationship.

The following example updates the relationship between the source volume 0005 at IP address 10.0.0.11 and the destination volume `volA_dst` on `svm_backup`:

```
cluster_src::> snapmirror update -source-path 10.0.0.11:/lun/0005
-destination-path svm_backup:volA_dst
```

= Resynchronize a replication relationship

:icons: font

:relative\_path: ./element-replication/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You need to resynchronize a replication relationship after you make a destination volume

writeable, after an update fails because a common Snapshot copy does not exist on the source and destination volumes, or if you want to change the replication policy for the relationship.

### About this task

Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.

You must specify the Element source path in the form *hostip:/lun/name*, where “lun” is the actual string “lun” and name is the name of the Element volume.

### Step

1. Resync the source and destination volumes:

```
snapmirror resync -source-path hostip:/lun/name -destination-path SVM:volume
|cluster://SVM/volume -type XDP -schedule schedule -policy policy
```

For complete command syntax, see the man page.

The following example resyncs the relationship between the source volume 0005 at IP address 10.0.0.11 and the destination volume *volA\_dst* on *svm\_backup*:

```
cluster_dst::> snapmirror resync -source-path 10.0.0.11:/lun/0005
-policy MirrorLatest -destination-path svm_backup:volA_dst
```

= Event and performance monitoring

:hardbreaks:

:linkattrs:

:relative\_path: ./event-performance-monitoring/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest./media/

= Monitor cluster performance with System Manager

= Monitor cluster performance using System Manager

:toc: macro

:toplevels: 1

:hardbreaks:

:icons: font

:linkattrs:

:relative\_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest./media/

The topics in this section show you how to manage cluster health and performance with System Manager in ONTAP 9.7 and later releases.

You can monitor cluster performance by viewing information about your system on the System Manager Dashboard. The Dashboard displays information about important alerts and notifications, the efficiency and capacity of storage tiers and volumes, the nodes that are available in a cluster, the status of the nodes in an HA pair, the most active applications and objects, and the performance metrics of a cluster or a node.

The Dashboard lets you determine the following information:

- **Health**: How healthy is the cluster?
- **Capacity**: What capacity is available on the cluster?
- **Performance**: How well is the cluster performing, based on latency, IOPS, and throughput?
- **Network**: How is the network configured with hosts and storage objects, such as ports, interfaces, and storage VMs?

In the Health and Capacity overviews, you can click → to view additional information and perform tasks.

In the Performance overview, you can view metrics based on the hour, the day, the week, the month, or the year.

In the Network overview, the number of each object in the network is displayed (for example, "8 NVMe/FC ports"). You can click on the numbers to view details about each network object.

= View performance on cluster dashboard

```
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ../
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest./media/
```

Use the dashboard to make informed decisions about workloads you might want to add or move. You can also look at peak usage times to plan for potential changes.

The performance values refresh every 3 seconds and the performance graph refreshes every 15 seconds.

## Steps

1. Click **Dashboard**.
2. Under **Performance**, select the interval.

= Identify hot volumes and other objects

```
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ../
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest./media/
```

Accelerate your cluster performance by identifying the frequently accessed volumes (hot volumes) and data (hot objects).

Beginning in ONTAP 9.10.1, you can use the Activity Tracking feature in File System Analytics to monitor hot objects in a volume.

## Steps

1. Click **Storage > Volumes**.

2. Filter the IOPS, latency, and throughput columns to view the frequently accessed volumes and data.

= Modify QoS  
:toc: macro  
:toplevels: 1  
:hardbreaks:  
:icons: font  
:linkattrs:  
:relative\_path: ./  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/

Beginning with ONTAP 9.8, when you provision storage, QoS is enabled by default. You can disable QoS or choose a custom QoS policy during the provisioning process. You can also modify QoS after your storage has been provisioned.

### Steps

1. In System Manager, click **Storage** and select **Volumes**.
2. Next to the volume for which you want to modify QoS, click  and select **Edit**.

= Monitor and manage cluster performance using the CLI

= Performance monitoring and management overview  
:icons: font  
:relative\_path: ./performance-admin/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You can set up basic performance monitoring and management tasks and identify and resolve common performance issues.

You can use these procedures to monitor and manage cluster performance if the following assumptions apply to your situation:

- You want to use best practices, not explore every available option.
- You want to display system status and alerts, monitor cluster performance, and perform root-cause analysis by using Active IQ Unified Manager (formerly OnCommand Unified Manager), in addition to the ONTAP command-line interface.
- You are using the ONTAP command-line interface to configure storage quality of service (QoS).

QoS is also available in System Manager, NSLM, WFA, VSC (VMware Plug-in), and APIs.

- You want to install Unified Manager by using a virtual appliance, instead of a Linux or Windows-based installation.
- You're willing to use a static configuration rather than DHCP to install the software.
- You can access ONTAP commands at the advanced privilege level.
- You are a cluster administrator with the "admin" role.

### Related information

If these assumptions are not correct for your situation, you should see the following resources:

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/../encryption-at-rest/..media/

Monitoring and maintaining cluster performance involves installing Active IQ Unified Manager software, setting up basic monitoring tasks, identifying performance issues, and making adjustments as needed.

= Verify that your VMware environment is supported

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/../encryption-at-rest/..media/

To successful install Active IQ Unified Manager, you must verify that your VMware environment meets the necessary requirements.

### Steps

1. Verify that your VMware infrastructure meets the sizing requirements for the installation of Unified Manager.
2. Go to the [Interoperability Matrix](#) to verify that you have a supported combination of the following

components:

- ONTAP version
- ESXi operating system version
- VMware vCenter Server version
- VMware Tools version
- Browser type and version

The [Interoperability Matrix](#) lists the supported configurations for Unified Manager.

3. Click the configuration name for the selected configuration.

Details for that configuration are displayed in the Configuration Details window.

4. Review the information in the following tabs:

- Notes

Lists important alerts and information that are specific to your configuration.

- Policies and Guidelines

Provides general guidelines for all configurations.

= Active IQ Unified Manager worksheet

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

Before you install, configure, and connect Active IQ Unified Manager, you should have specific information about your environment readily available. You can record the information in the worksheet.

== Unified Manager installation information

| Virtual machine on which software is deployed | Your value |
|-----------------------------------------------|------------|
| ESXi server IP address                        |            |
| Host fully qualified domain name              |            |
| Host IP address                               |            |
| Network mask                                  |            |
| Gateway IP address                            |            |
| Primary DNS address                           |            |

|                           |  |

| LDAP bind distinguished name                  |                    |
| LDAP bind password                            |                    |
| Active Directory administrator name           |                    |
| Active Directory password                     |                    |
| Authentication server base distinguished name |                    |
| Authentication server host name or IP address |                    |

== Cluster information

Capture the following information for each cluster on Unified Manager.

| Cluster 1 of N                             | Your value |
|--------------------------------------------|------------|
| Host name or cluster-management IP address |            |

|                                                                                                                                               |  |
|-----------------------------------------------------------------------------------------------------------------------------------------------|--|
| ONTAP administrator user name                                                                                                                 |  |
|  The administrator must have been assigned the "admin" role. |  |
| ONTAP administrator password                                                                                                                  |  |
| Protocol (HTTP or HTTPS)                                                                                                                      |  |

## Related information

### [Administrator authentication and RBAC](#)

= Install Active IQ Unified Manager

= Download and deploy Active IQ Unified Manager

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

To install the software, you must download the virtual appliance (VA) installation file and then use a VMware vSphere Client to deploy the file to a VMware ESXi server. The VA is available in an OVA file.

## Steps

1. Go to the **NetApp Support Site Software Download** page and locate Active IQ Unified Manager.

<https://mysupport.netapp.com/products/index.html>

2. Select **VMware vSphere** in the **Select Platform** drop-down menu and click **Go!**

3. Save the “OVA” file to a local or network location that is accessible to your VMware vSphere Client.

4. In VMware vSphere Client, click **File > Deploy OVF Template**.

5. Locate the “OVA” file and use the wizard to deploy the virtual appliance on the ESXi server.

You can use the **Properties** tab in the wizard to enter your static configuration information.

6. Power on the VM.

7. Click the **Console** tab to view the initial boot process.

8. Follow the prompt to install VMware Tools on the VM.

9. Configure the time zone.

10. Enter a maintenance user name and password.

11. Go to the URL displayed by the VM console.

= Configure initial Active IQ Unified Manager settings

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

The Active IQ Unified Manager Initial Setup dialog box appears when you first access the web UI, which enables you to configure some initial settings and to add clusters.

## Steps

1. Accept the default AutoSupport enabled setting.
2. Enter the NTP server details, the maintenance user email address, the SMTP server host name, and additional SMTP options, and then click **Save**.

## After you finish

When the initial setup is complete, the Cluster Data Sources page is displayed where you can add the cluster details.

= Specify the clusters to be monitored

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest../media/

You must add a cluster to an Active IQ Unified Manager server to monitor the cluster, view the cluster discovery status, and monitor its performance.

## What you'll need

- You must have the following information:
  - Host name or cluster-management IP address

The host name is the fully qualified domain name (FQDN) or short name that Unified Manager uses to connect to the cluster. This host name must resolve to the cluster-management IP address.

The cluster-management IP address must be the cluster-management LIF of the administrative storage virtual machine (SVM). If you use a node-management LIF, the operation fails.

- ONTAP administrator user name and password
- Type of protocol (HTTP or HTTPS) that can be configured on the cluster and the port number of the cluster
- You must have the Application Administrator or Storage Administrator role.
- The ONTAP administrator must have the ONTAPI and SSH administrator roles.
- The Unified Manager FQDN must be able to ping ONTAP.

You can verify this by using the ONTAP command `ping -node node_name -destination Unified_Manager_FQDN`.

## About this task

For a MetroCluster configuration, you must add both the local and remote clusters, and the clusters must be configured correctly.

## Steps

1. Click **Configuration > Cluster Data Sources**.
2. From the Clusters page, click **Add**.
3. In the **Add Cluster** dialog box, specify the required values, such as the host name or IP address (IPv4 or IPv6) of the cluster, user name, password, protocol for communication, and port number.

By default, the HTTPS protocol is selected.

You can change the cluster-management IP address from IPv6 to IPv4 or from IPv4 to IPv6. The new IP address is reflected in the cluster grid and the cluster configuration page after the next monitoring cycle finishes.

4. Click **Add**.

5. If HTTPS is selected, perform the following steps:

- a. In the **Authorize Host** dialog box, click **View Certificate** to view the certificate information about the cluster.
- b. Click **Yes**.

Unified Manager checks the certificate only when the cluster is initially added, but does not check it for each API call to ONTAP.

If the certificate has expired, you cannot add the cluster. You must renew the SSL certificate and then add the cluster.

6. **Optional:** View the cluster discovery status:

- a. Review the cluster discovery status from the **Cluster Setup** page.

The cluster is added to the Unified Manager database after the default monitoring interval of approximately 15 minutes.

= Set up basic monitoring tasks

= Perform daily monitoring

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can perform daily monitoring to ensure that you do not have any immediate performance issues that require attention.

### Steps

1. From the Active IQ Unified Manager UI, go to the **Event Inventory** page to view all current and obsolete events.
2. From the **View** option, select **Active Performance Events** and determine what action is required.

= Use weekly and monthly performance trends to identify performance issues

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

Identifying performance trends can assist you in identifying whether the cluster is being overused or underused by analyzing volume latency. You can use similar steps to identify CPU, network, or other system bottlenecks.

### Steps

1. Locate the volume that you suspect is being underused or overused.

2. On the **Volume Details** tab, click **30 d** to display the historical data.
3. In the "Break down data by" drop-down menu, select **Latency**, and then click **Submit**.
4. Deselect **Aggregate** in the cluster components comparison chart, and then compare the cluster latency with the volume latency chart.
5. Select **Aggregate** and deselect all other components in the cluster components comparison chart, and then compare the aggregate latency with the volume latency chart.
6. Compare the reads/writes latency chart to the volume latency chart.
7. Determine whether client application loads have caused a workload contention and rebalance workloads as needed.
8. Determine whether the aggregate is overused and causing contention and rebalance workloads as needed.

= Use performance thresholds to generate event notifications

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

Events are notifications that the Active IQ Unified Manager generates automatically when a predefined condition occurs, or when a performance counter value crosses a threshold. Events help you identify performance issues in the clusters you are monitoring. You can configure alerts to send email notification automatically when events of certain severity types occur.

= Set performance thresholds

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can set performance thresholds to monitor critical performance issues. User-defined thresholds trigger a warning or a critical event notification when the system approaches or exceeds the defined threshold.

## Steps

1. Create the Warning and Critical event thresholds:
  - a. Select **Configuration > Performance Thresholds**.
  - b. Click **Create**.
  - c. Select the object type and specify a name and description of the policy.
  - d. Select the object counter condition and specify the limit values that define Warning and Critical events.
  - e. Select the duration of time that the limit values must be breached for an event to be sent, and then click **Save**.
2. Assign the threshold policy to the storage object.
  - a. Go to the Inventory page for the same cluster object type that you previously selected and choose the **Performance** from the View option.
  - b. Select the object to which you want to assign the threshold policy, and then click **Assign Threshold Policy**.

- c. Select the policy you previously created, and then click **Assign Policy**.

### Example

You can set user-defined thresholds to learn about critical performance issues. For example, if you have a Microsoft Exchange Server and you know that it crashes if volume latency exceeds 20 milliseconds, you can set a warning threshold at 12 milliseconds and a critical threshold at 15 milliseconds. With this threshold setting, you can receive notifications when the volume latency exceeds the limit.

The screenshot shows a configuration dialog for an alert. On the left, there's a dropdown menu labeled "Object Counter Condition\*" with "Average Latency ms/op" selected. To the right of the dropdown are two threshold fields: "Warning" (set to 12 ms/op) and "Critical" (set to 15 ms/op). Both threshold fields have their unit "ms/op" displayed next to them.

= Add alerts

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can configure alerts to notify you when a particular event is generated. You can configure alerts for a single resource, for a group of resources, or for events of a particular severity type. You can specify the frequency with which you want to be notified and associate a script to the alert.

### What you'll need

- You must have configured notification settings such as the user email address, SMTP server, and SNMP trap host to enable the Active IQ Unified Manager server to use these settings to send notifications to users when an event is generated.
- You must know the resources and events for which you want to trigger the alert, and the user names or email addresses of the users that you want to notify.
- If you want to have a script execute based on the event, you must have added the script to Unified Manager by using the Scripts page.
- You must have the Application Administrator or Storage Administrator role.

### About this task

You can create an alert directly from the Event details page after receiving an event in addition to creating an alert from the Alert Setup page, as described here.

### Steps

1. In the left navigation pane, click **Storage Management > Alert Setup**.
2. In the **Alert Setup** page, click **Add**.
3. In the **Add Alert** dialog box, click **Name**, and enter a name and description for the alert.
4. Click **Resources**, and select the resources to be included in or excluded from the alert.

You can set a filter by specifying a text string in the **Name contains** field to select a group of resources. Based on the text string that you specify, the list of available resources displays only those resources that match the filter rule. The text string that you specify is case-sensitive.

If a resource conforms to both the include and exclude rules that you have specified, the exclude rule takes precedence over the include rule, and the alert is not generated for events related to the excluded resource.

5. Click **Events**, and select the events based on the event name or event severity type for which you want to trigger an alert.

To select more than one event, press the Ctrl key while you make your selections.

6. Click **Actions**, and select the users that you want to notify, choose the notification frequency, choose whether an SNMP trap will be sent to the trap receiver, and assign a script to be executed when an alert is generated.

If you modify the email address that is specified for the user and reopen the alert for editing, the Name field appears blank because the modified email address is no longer mapped to the user that was previously selected. Also, if you modified the email address of the selected user from the Users page, the modified email address is not updated for the selected user.

You can also choose to notify users through SNMP traps.

7. Click **Save**.

#### Example of adding an alert

This example shows how to create an alert that meets the following requirements:

- Alert name: HealthTest
- Resources: includes all volumes whose name contains "abc" and excludes all volumes whose name contains "xyz"
- Events: includes all critical health events
- Actions: includes "[sample@domain.com](mailto:sample@domain.com)", a "Test" script, and the user has to be notified every 15 minutes

Perform the following steps in the Add Alert dialog box:

1. Click **Name**, and enter HealthTest in the **Alert Name** field.
2. Click **Resources**, and in the Include tab, select **Volumes** from the drop-down list.
  - a. Enter abc in the **Name contains** field to display the volumes whose name contains "abc".
  - b. Select <<All Volumes whose name contains 'abc'>> from the Available Resources area, and move it to the Selected Resources area.
  - c. Click **Exclude**, and enter xyz in the **Name contains** field, and then click **Add**.
3. Click **Events**, and select **Critical** from the Event Severity field.
4. Select **All Critical Events** from the Matching Events area, and move it to the Selected Events area.
5. Click **Actions**, and enter [sample@domain.com](mailto:sample@domain.com) in the Alert these users field.
6. Select **Remind every 15 minutes** to notify the user every 15 minutes.

You can configure an alert to repeatedly send notifications to the recipients for a specified time. You should determine the time from which the event notification is active for the alert.

7. In the Select Script to Execute menu, select **Test** script.
8. Click **Save**.

= Configure alert settings

```
:icons: font
:relative_path: ./performance-admin/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/
```

You can specify which events from Active IQ Unified Manager trigger alerts, the email recipients for those alerts, and the frequency for the alerts.

### What you'll need

You must have the Application Administrator role.

### About this task

You can configure unique alert settings for the following types of performance events:

- Critical events triggered by breaches of user-defined thresholds
- Warning events triggered by breaches of user-defined thresholds, system-defined thresholds, or dynamic thresholds

By default, email alerts are sent to Unified Manager admin users for all new events. You can have email alerts sent to other users by adding those users' email addresses.

To disable alerts from being sent for certain types of events, you must clear all of the check boxes in an event category. This action does not stop events from appearing in the user interface.

### Steps

1. In the left navigation pane, select **Storage Management > Alert Setup**.

The Alert Setup page is displayed.

2. Click **Add** and configure the appropriate settings for each of the event types.

To have email alerts sent to multiple users, enter a comma between each email address.

3. Click **Save**.

= Identify performance issues in Active IQ Unified Manager

```
:icons: font
:relative_path: ./performance-admin/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/
```

If a performance event occurs, you can locate the source of the issue within Active IQ Unified Manager and use other tools to fix it. You might receive an email notification of an event or notice the event during daily monitoring.

### Steps

1. Click the link in the email notification, which takes you directly to the storage object having a performance event.

| If you...                                 | Then...                                                  |
|-------------------------------------------|----------------------------------------------------------|
| Receive an email notification of an event | Click the link to go directly to the event details page. |

Notice the event while analyzing the Event Inventory page

Select the event to go directly to the event details page.

2. If the event has crossed a system-defined threshold, follow the suggested actions in the UI to troubleshoot the issue.
3. If the event has crossed a user-defined threshold, analyze the event to determine if you need to take action.
4. If the issue persists, check the following settings:
  - Protocol settings on the storage system
  - Network settings on any Ethernet or fabric switches
  - Network settings on the storage system
  - Disk layout and aggregate metrics on the storage system
5. If the issue persists, contact technical support for assistance.

= Use Active IQ Digital Advisor to view system performance

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

For any ONTAP system that sends AutoSupport telemetry to NetApp, you can view extensive performance and capacity data. Active IQ shows system performance over a longer period than you can see in System Manager.

You can view graphs of CPU utilization, latency, IOPS, IOPS by protocol, and network throughput. You can also download this data in .csv format for analysis in other tools.

In addition to this performance data, Active IQ can show you storage efficiency by workload and compare that efficiency to the expected efficiency for that type of workload. You can view capacity trends and see an estimate of how much additional storage you might need to add in a given time frame.

-  • Storage Efficiency is available at the customer, cluster, and node level on the left-hand-side of the main dashboard.  
• Performance is available at the cluster and node level on the left-hand-side of the main dashboard.

= Manage performance issues

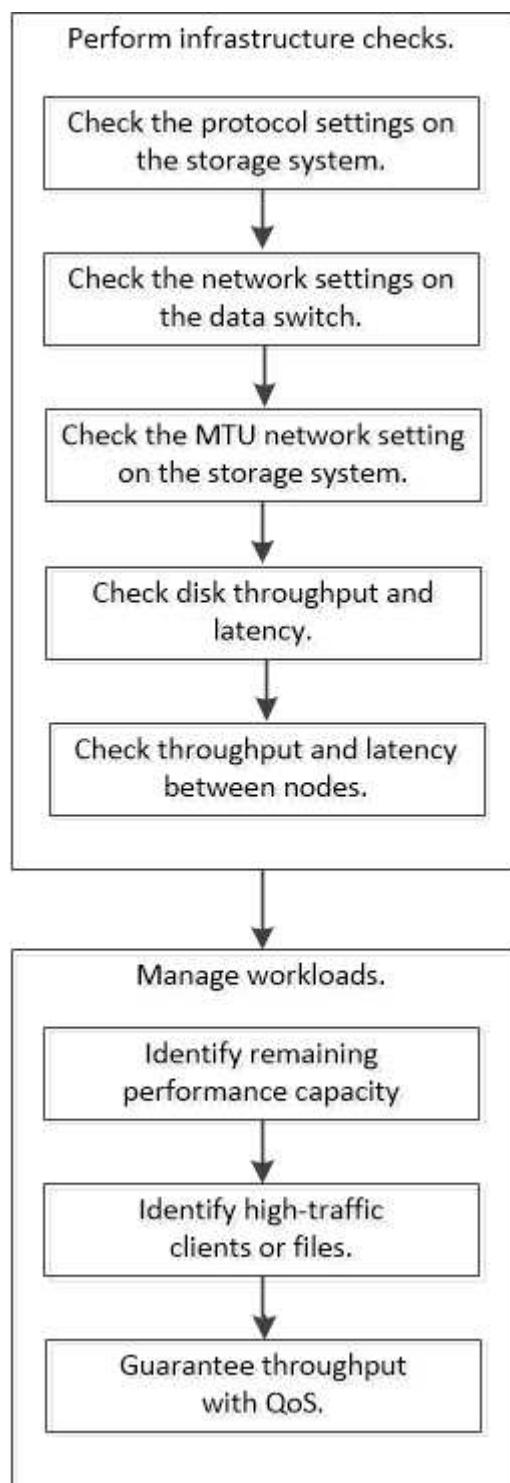

= Performance management workflow

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

Once you have identified a performance issue, you can conduct some basic diagnostic checks of your infrastructure to rule out obvious configuration errors. If those don't pinpoint the problem, you can start looking at workload management issues.

= Perform basic infrastructure checks

= Check protocol settings on the storage system

= Check the NFS TCP maximum transfer size

:icons: font

```
:relative_path: ./performance-admin/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/
```

For NFS, you can check whether the TCP maximum transfer size for reads and writes might be causing a performance issue. If you think the size is slowing performance, you can increase it.

#### What you'll need

- You must have cluster administrator privileges to perform this task.
- You must use advanced privilege level commands for this task.

#### Steps

1. Change to the advanced privilege level:

```
set -privilege advanced
```

2. Check the TCP maximum transfer size:

```
vserver nfs show -vserver vserver_name -instance
```

3. If the TCP maximum transfer size is too small, increase the size:

```
vserver nfs modify -vserver vserver_name -tcp-max-xfer-size integer
```

4. Return to the administrative privilege level:

```
set -privilege admin
```

#### Example

The following example changes the TCP maximum transfer size of SVM1 to 1048576:

```
cluster1::>*> vserver nfs modify -vserver SVM1 -tcp-max-xfer-size 1048576
```

= Check the iSCSI TCP read/write size

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

For iSCSI, you can check the TCP read/write size to determine if the size setting is creating a performance issue. If the size is the source of an issue, you can correct it.

#### What you'll need

Advanced privilege level commands are required for this task.

#### Steps

1. Change to advanced privilege level:

```
set -privilege advanced
```

2. Check the TCP window size setting:

```
vserver iscsi show -vserver vserver_name -instance
```

3. Modify the TCP window size setting:

```
vserver iscsi modify -vserver vserver_name -tcp-window-size integer
```

4. Return to administrative privilege:

```
set -privilege admin
```

### Example

The following example changes the TCP window size of SVM1 to 131,400 bytes:

```
cluster1::> vserver iscsi modify -vserver vs1 -tcp-window-size 131400
```

= Check the CIFS multiplex settings

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/../media/

If slow CIFS network performance causes a performance issue, you can modify the multiplex settings to improve and correct it.

### Steps

1. Check the CIFS multiplex setting:

```
vserver cifs options show -vserver vserver_name -instance
```

2. Modify the CIFS multiplex setting:

```
vserver cifs options modify -vserver vserver_name -max-mpx integer
```

### Example

The following example changes the maximum multiplex count on SVM1 to 255:

```
cluster1::> vserver cifs options modify -vserver SVM1 -max-mpx 255
```

= Check the FC adapter port speed

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/../media/

The adapter target port speed should match the speed of the device to which it connects, to optimize performance. If the port is set to autonegotiation, it can take longer to reconnect after a takeover and giveback or other interruption.

## What you'll need

All LIFs that use this adapter as their home port must be offline.

## Steps

1. Take the adapter offline:

```
network fcp adapter modify -node nodename -adapter adapter -state down
```

2. Check the maximum speed of the port adapter:

```
fcp adapter show -instance
```

3. Change the port speed, if necessary:

```
network fcp adapter modify -node nodename -adapter adapter -speed {1|2|4|8|10|16|auto}
```

4. Bring the adapter online:

```
network fcp adapter modify -node nodename -adapter adapter -state up
```

5. Bring all the LIFs on the adapter online:

```
network interface modify -vserver * -lif * { -home-node node1 -home-port e0c } -status-admin up
```

## Example

The following example changes the port speed of adapter 0d on node1 to 2 Gbps:

```
cluster1::> network fcp adapter modify -node node1 -adapter 0d -speed 2
```

= Check the network settings on the data switches

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

Although you must maintain the same MTU settings on your clients, servers and storage systems (that is, network endpoints), intermediate network devices such as NICs and switches should be set to their maximum MTU values to ensure that performance is not impacted.

For best performance, all components in the network must be able to forward jumbo frames (9000 bytes IP, 9022 bytes including Ethernet). Data switches should be set to at least 9022 bytes, but a typical value of 9216 is possible with most switches.

## Procedure

For data switches, check that the MTU size is set to 9022 or higher.

For more information, see the switch vendor documentation.

= Check the MTU network setting on the storage system  
:icons: font  
:relative\_path: ./performance-admin/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can change the network settings on the storage system if they are not the same as on the client or other network endpoints. Whereas the management network MTU setting is set to 1500, the data network MTU size should be 9000.

#### == About this task

All ports within a broadcast-domain have the same MTU size, with the exception of the eOM port handling management traffic. If the port is part of a broadcast-domain, use the `broadcast-domain modify` command to change the MTU for all ports within the modified broadcast-domain.

Note that intermediate network devices such as NICs and data switches can be set to higher MTU sizes than network endpoints. For more information, see [Check the network settings on the data switches](#).

#### Steps

1. Check the MTU port setting on the storage system:

```
network port show -instance
```

2. Change the MTU on the broadcast domain used by the ports:

```
network port broadcast-domain modify -ipspace ipspace -broadcast-domain
broadcast_domain -mtu new_mtu
```

#### Example

The following example changes the MTU port setting to 9000:

```
network port broadcast-domain modify -ipspace Cluster -broadcast-domain
Cluster -mtu 9000
```

= Check disk throughput and latency  
:icons: font  
:relative\_path: ./performance-admin/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can check the disk throughput and latency metrics for cluster nodes to assist you in troubleshooting.

#### About this task

Advanced privilege level commands are required for this task.

#### Steps

1. Change to advanced privilege level:

```
set -privilege advanced
```

2. Check the disk throughput and latency metrics:

```
statistics disk show -sort-key latency
```

## Example

The following example displays the totals in each user read or write operation for node2 on cluster1:

```
::*:> statistics disk show -sort-key latency
cluster1 : 8/24/2015 12:44:15
 Busy Total Read Write Read Write *Latency
 Disk Node (%) Ops Ops Ops (Bps) (Bps) (us)
----- ----- ----- ----- ----- ----- ----- -----
1.10.20 node2 4 5 3 2 95232 367616 23806
1.10.8 node2 4 5 3 2 138240 386048 22113
1.10.6 node2 3 4 2 2 48128 371712 19113
1.10.19 node2 4 6 3 2 102400 443392 19106
1.10.11 node2 4 4 2 2 122880 408576 17713
```

= Check throughput and latency between nodes

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can use the `network test-path` command to identify network bottlenecks, or to prequalify network paths between nodes. You can run the command between intercluster nodes or intracluster nodes.

## What you'll need

- You must be a cluster administrator to perform this task.
- Advanced privilege level commands are required for this task.
- For an intercluster path, the source and destination clusters must be peered.

## About this task

Occasionally, network performance between nodes may not meet expectations for your path configuration. A 1 Gbps transmission rate for the kind of large data transfers seen in SnapMirror replication operations, for example, would not be consistent with a 10 GbE link between the source and destination clusters.

You can use the `network test-path` command to measure throughput and latency between nodes. You can run the command between intercluster nodes or intracluster nodes.

The test saturates the network path with data, so you should run the command when the system is not busy and when network traffic between nodes is not excessive. The test times out after ten seconds. The command can be run only between ONTAP 9 nodes.

The session-type option identifies the type of operation you are running over the network path—for example, "AsyncMirrorRemote" for SnapMirror replication to a remote destination. The type dictates the

amount of data used in the test. The following table defines the session types:

| Session Type       | Description                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AsyncMirrorLocal   | Settings used by SnapMirror between nodes in the same cluster                                                                                                             |
| AsyncMirrorRemote  | Settings used by SnapMirror between nodes in different clusters (default type)                                                                                            |
| RemoteDataTransfer | Settings used by ONTAP for remote data access between nodes in the same cluster (for example, an NFS request to a node for a file stored in a volume on a different node) |

## Steps

1. Change to advanced privilege level:

```
set -privilege advanced
```

2. Measure throughput and latency between nodes:

```
network test-path -source-node source_nodename |local -destination-cluster destination_clustername -destination-node destination_nodename -session-type Default|AsyncMirrorLocal|AsyncMirrorRemote|SyncMirrorRemote|RemoteDataTransfer
```

The source node must be in the local cluster. The destination node can be in the local cluster or in a peered cluster. A value of "local" for `-source-node` specifies the node on which you are running the command.

The following command measures throughput and latency for SnapMirror-type replication operations between `node1` on the local cluster and `node3` on `cluster2`:

```
cluster1::> network test-path -source-node node1 -destination-cluster cluster2 -destination-node node3 -session-type AsyncMirrorRemote
Test Duration: 10.88 secs
Send Throughput: 18.23 MB/sec
Receive Throughput: 18.23 MB/sec
MB sent: 198.31
MB received: 198.31
Avg latency in ms: 2301.47
Min latency in ms: 61.14
Max latency in ms: 3056.86
```

3. Return to administrative privilege:

```
set -privilege admin
```

## After you finish

If performance does not meet expectations for the path configuration, you should check node performance statistics, use available tools to isolate the problem in the network, check switch settings, and so forth.

= Manage workloads

= Identify remaining performance capacity

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

Performance capacity, or *headroom*, measures how much work you can place on a node or an aggregate before performance of workloads on the resource begins to be affected by latency. Knowing the available performance capacity on the cluster helps you provision and balance workloads.

### What you'll need

Advanced privilege level commands are required for this task.

### About this task

You can use the following values for the `-object` option to collect and display headroom statistics:

- For CPUs, `resource_headroom_cpu`.
- For aggregates, `resource_headroom_aggr`.

You can also complete this task using System Manager and Active IQ Unified Manager.

### Steps

1. Change to advanced privilege level:

```
set -privilege advanced
```

2. Start real-time headroom statistics collection:

```
statistics start -object resource_headroom_cpu|aggr
```

For complete command syntax, see the man page.

3. Display real-time headroom statistics information:

```
statistics show -object resource_headroom_cpu|aggr
```

For complete command syntax, see the man page.

4. Return to administrative privilege:

```
set -privilege admin
```

### Example

The following example displays the average hourly headroom statistics for cluster nodes.

You can compute the available performance capacity for a node by subtracting the `current_utilization`

counter from the optimal\_point\_utilization counter. In this example, the utilization capacity for CPU\_sti2520-213 is -14% (72%-86%), which suggests that the CPU has been overutilized on average for the past hour.

You could have specified ewma\_daily, ewma\_weekly, or ewma\_monthly to get the same information averaged over longer periods of time.

```
sti2520-213:1454963690::>*> statistics show -object resource_headroom_cpu
-raw -counter ewma_hourly
(statistics show)

Object: resource_headroom_cpu
Instance: CPU_sti2520-213
Start-time: 2/9/2016 16:06:27
End-time: 2/9/2016 16:06:27
Scope: sti2520-213

 Counter Value

ewma_hourly
 current_ops 4376
 current_latency 37719
 current_utilization 86
 optimal_point_ops 2573
 optimal_point_latency 3589
 optimal_point_utilization 72
 optimal_point_confidence_factor 1

Object: resource_headroom_cpu
Instance: CPU_sti2520-214
Start-time: 2/9/2016 16:06:27
End-time: 2/9/2016 16:06:27
Scope: sti2520-214

 Counter Value

ewma_hourly
 current_ops 0
 current_latency 0
 current_utilization 0
 optimal_point_ops 0
 optimal_point_latency 0
 optimal_point_utilization 71
 optimal_point_confidence_factor 1

2 entries were displayed.
```

```
= Identify high-traffic clients or files
:icons: font
:relative_path: ./performance-admin/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/
```

You can use ONTAP Active Objects technology to identify clients or files that are responsible for a disproportionately large amount of cluster traffic. Once you have identified these "top" clients or files, you can rebalance cluster workloads or take other steps to resolve the issue.

### What you'll need

You must be a cluster administrator to perform this task.

### Steps

1. View the top clients accessing the cluster:

```
statistics top client show -node node_name -sort-key sort_column -interval
seconds_between_updates -iterations iterations -max number_of_instances
```

For complete command syntax, see the man page.

The following command displays the top clients accessing cluster1:

```
cluster1::> statistics top client show

cluster1 : 3/23/2016 17:59:10

*Total
Client Vserver Node Protocol Ops
----- -----
172.17.180.170 vs4 sideropl-vsimg4 nfs 668
172.17.180.169 vs3 sideropl-vsimg3 nfs 337
172.17.180.171 vs3 sideropl-vsimg3 nfs 142
172.17.180.170 vs3 sideropl-vsimg3 nfs 137
172.17.180.123 vs3 sideropl-vsimg3 nfs 137
172.17.180.171 vs4 sideropl-vsimg4 nfs 95
172.17.180.169 vs4 sideropl-vsimg4 nfs 92
172.17.180.123 vs4 sideropl-vsimg4 nfs 92
172.17.180.153 vs3 sideropl-vsimg3 nfs 0
```

2. View the top files accessed on the cluster:

```
statistics top file show -node node_name -sort-key sort_column -interval
seconds_between_updates -iterations iterations -max number_of_instances
```

For complete command syntax, see the man page.

The following command displays the top files accessed on cluster1:

```
cluster1::> statistics top file show

cluster1 : 3/23/2016 17:59:10

= Guarantee throughput with QoS

= Guarantee throughput with QoS overview

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

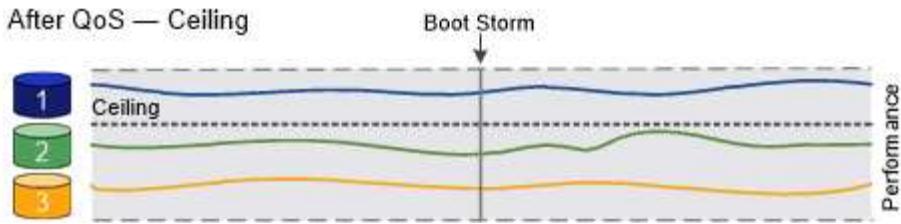

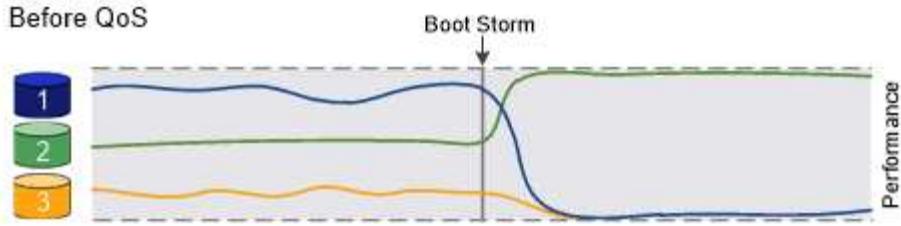

You can use storage quality of service (QoS) to guarantee that performance of critical workloads is not degraded by competing workloads. You can set a throughput *ceiling* on a competing workload to limit its impact on system resources, or set a throughput *floor* for a critical workload, ensuring that it meets minimum throughput targets, regardless of demand by competing workloads. You can even set a ceiling and floor for the same workload.

== About throughput ceilings (QoS Max)

A throughput ceiling limits throughput for a workload to a maximum number of IOPS or MBps, or IOPS and MBps. In the figure below, the throughput ceiling for workload 2 ensures that it does not "bully" workloads 1 and 3.

A *policy group* defines the throughput ceiling for one or more workloads. A workload represents the I/O operations for a *storage object*: a volume, file, qtree or LUN, or all the volumes, files, qtrees, or LUNs in an SVM. You can specify the ceiling when you create the policy group, or you can wait until after you monitor workloads to specify it.

 Throughput to workloads might exceed the specified ceiling by up to 10%, especially if a workload experiences rapid changes in throughput. The ceiling might be exceeded by up to 50% to handle bursts. Bursts occur on single nodes when tokens accumulate up to 150%

== About throughput floors (QoS Min)

A throughput floor guarantees that throughput for a workload does not fall below a minimum number of IOPS or MBps, or IOPS and MBps. In the figure below, the throughput floors for workload 1 and workload 3 ensure that they meet minimum throughput targets, regardless of demand by workload 2.

As the examples suggest, a throughput ceiling throttles throughput directly. A throughput floor throttles throughput indirectly, by giving priority to the workloads for which the floor has been set.

You can specify the floor when you create the policy group, or you can wait until after you monitor workloads to specify it.

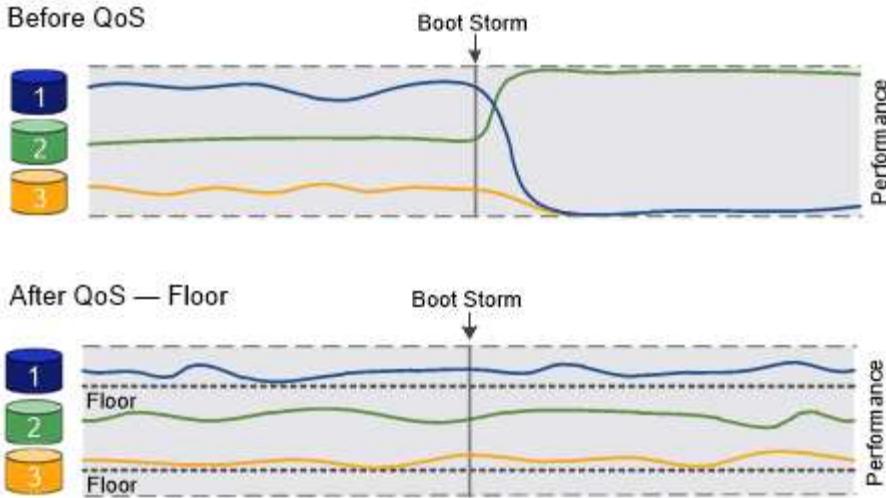

Beginning in ONTAP 9.13.1, you can set throughput floors at the SVM scope with [Adaptive policy group templates](#). In releases of ONTAP before 9.13.1, a policy group that defines a throughput floor cannot be applied to an SVM.

In releases before ONTAP 9.7, throughput floors are guaranteed when there is sufficient performance capacity available.

+  
In ONTAP 9.7 and later, throughput floors can be guaranteed even when there is insufficient performance capacity available. This new floor behavior is called floors v2. To meet the guarantees, floors v2 can result in higher latency on workloads without a throughput floor or on work that exceeds the floor settings. Floors v2 applies to both QoS and adaptive QoS.

+  
The option of enabling/disabling the new behavior of floors v2 is available in ONTAP 9.7P6 and later. A workload might fall below the specified floor during critical operations like volume move trigger-cutover. Even when sufficient capacity is available and critical operations are not taking place, throughput to a workload might fall below the specified floor by up to 5%. If floors are overprovisioned and there is no performance capacity, some workloads might fall below the specified floor.

## == About shared and non-shared QoS policy groups

Beginning with ONTAP 9.4, you can use a *non-shared* QoS policy group to specify that the defined throughput ceiling or floor applies to each member workload individually. Behavior of *shared* policy groups depends on the policy type:

- For throughput ceilings, the total throughput for the workloads assigned to the shared policy group cannot exceed the specified ceiling.
- For throughput floors, the shared policy group can be applied to a single workload only.

## == About adaptive QoS

Ordinarily, the value of the policy group you assign to a storage object is fixed. You need to change the value manually when the size of the storage object changes. An increase in the amount of space used on a volume, for example, usually requires a corresponding increase in the throughput ceiling specified for the volume.

*Adaptive QoS* automatically scales the policy group value to workload size, maintaining the ratio of IOPS to TBs|GBs as the size of the workload changes. That is a significant advantage when you are managing hundreds or thousands of workloads in a large deployment.

You typically use adaptive QoS to adjust throughput ceilings, but you can also use it to manage throughput floors (when workload size increases). Workload size is expressed as either the allocated space for the storage object or the space used by the storage object.

Used space is available for throughput floors in ONTAP 9.5 and later. It is not supported for throughput floors in ONTAP 9.4 and earlier.

- An *allocated space* policy maintains the IOPS/TB|GB ratio according to the nominal size of the storage object. If the ratio is 100 IOPS/GB, a 150 GB volume will have a throughput ceiling of 15,000 IOPS for as long as the volume remains that size. If the volume is resized to 300 GB, adaptive QoS adjusts the throughput ceiling to 30,000 IOPS.
- A *used space* policy (the default) maintains the IOPS/TB|GB ratio according to the amount of actual data stored before storage efficiencies. If the ratio is 100 IOPS/GB, a 150 GB volume that has 100 GB of data stored would have a throughput ceiling of 10,000 IOPS. As the amount of used space changes, adaptive QoS adjusts the throughput ceiling according to the ratio.

Beginning with ONTAP 9.5, you can specify an I/O block size for your application that enables a throughput limit to be expressed in both IOPS and MBps. The MBps limit is calculated from the block size multiplied by the

IOPS limit. For example, an I/O block size of 32K for an IOPS limit of 6144IOPS/TB yields an MBps limit of 192MBps.

You can expect the following behavior for both throughput ceilings and floors:

- When a workload is assigned to an adaptive QoS policy group, the ceiling or floor is updated immediately.
- When a workload in an adaptive QoS policy group is resized, the ceiling or floor is updated in approximately five minutes.

Throughput must increase by at least 10 IOPS before updates take place.

Adaptive QoS policy groups are always non-shared: the defined throughput ceiling or floor applies to each member workload individually.

Beginning with ONTAP 9.6, throughput floors are supported on ONTAP Select premium with SSD.

#### ==== Adaptive policy group template

Beginning in ONTAP 9.13.1, you can set an adaptive QoS template on an SVM. Adaptive policy group templates enable you to set throughput floors and ceilings for all volumes in an SVM.

Adaptive policy group templates can only be set after the SVM has been created. Use the `vserver modify` command with the `-qos-adaptive-policy-group-template` parameter to set the policy.

When you set an adaptive policy group template, volumes created or migrated after setting the policy automatically inherit the policy. Any volumes existing on the SVM are not impacted when you assign the policy template. If you disable the policy on the SVM, any volume subsequently migrated to or created on the SVM will not receive the policy. Disabling the adaptive policy group template does not impact volumes that inherited the policy template as they retain the policy template.

For more information, see [Set an adaptive policy group template](#).

#### == General support

The following table shows the differences in support for throughput ceilings, throughput floors, and adaptive QoS.

| Resource or feature | Throughput ceiling | Throughput floor                                                                                                 | Throughput floor v2                                                                                          | Adaptive QoS  |
|---------------------|--------------------|------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|---------------|
| ONTAP 9 version     | All                | 9.2 and later                                                                                                    | 9.7 and later                                                                                                | 9.3 and later |

\\*Beginning with ONTAP 9.8, NFS access is supported in qtrees in FlexVol and FlexGroup volumes with NFS enabled. Beginning with ONTAP 9.9.1, SMB access is also supported in qtrees in FlexVol and FlexGroup volumes with SMB enabled.

== Supported workloads for adaptive QoS

The following table shows workload support for adaptive QoS by ONTAP 9 version. Root volumes, load-sharing mirrors, and data protection mirrors are not supported.

| <b>Workload support - adaptive QoS</b> | <b>ONTAP 9.3</b> | <b>ONTAP 9.4 - 9.13.0</b> | <b>ONTAP 9.13.1 and later</b> |
|----------------------------------------|------------------|---------------------------|-------------------------------|
| Volume                                 | yes              | yes                       | yes                           |
| File                                   | no               | yes                       | yes                           |
| LUN                                    | no               | yes                       | yes                           |
| SVM                                    | no               | no                        | yes                           |
| FlexGroup volume                       | no               | yes                       | yes                           |
| Multiple workloads per policy group    | yes              | yes                       | yes                           |
| Non-shared policy groups               | yes              | yes                       | yes                           |

== Maximum number of workloads and policy groups

The following table shows the maximum number of workloads and policy groups by ONTAP 9 version.

| <b>Workload support</b>       | <b>ONTAP 9.3 and earlier</b> | <b>ONTAP 9.4 and later</b> |
|-------------------------------|------------------------------|----------------------------|
| Maximum workloads per cluster | 12,000                       | 40,000                     |

| Workload support           | ONTAP 9.3 and earlier | ONTAP 9.4 and later |
|----------------------------|-----------------------|---------------------|
| Maximum workloads per node | 12,000                | 40,000              |
| Maximum policy groups      | 12,000                | 12,000              |

= Enable or disable throughput floors v2

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

You can enable or disable throughput floors v2 on AFF. The default is enabled. With floors v2 enabled, throughput floors can be met when controllers are heavily used at the expense of higher latency on other workloads. Floors v2 applies to both QoS and Adaptive QoS.

### Steps

1. Change to advanced privilege level:

```
set -privilege advanced
```

2. Enter one of the following commands:

| If you want to... | Use this command:                                  |
|-------------------|----------------------------------------------------|
| Disable floors v2 | qos settings throughput-floors-v2<br>-enable false |
| Enable floors v2  | qos settings throughput-floors-v2<br>-enable true  |

To disable throughput floors v2 in an MetroCluster cluster, you must run the

qos settings throughput-floors-v2 -enable false

command on both the source and destination clusters.

```
cluster1::> qos settings throughput-floors-v2 -enable false
```

= Storage QoS workflow

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

If you already know the performance requirements for the workloads you want to manage with QoS, you can specify the throughput limit when you create the policy group. Otherwise, you can wait until after you monitor the workloads to specify the limit.

= Set a throughput ceiling with QoS  
:icons: font  
:relative\_path: ./performance-admin/  
:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/./media/

You can use the `max-throughput` field for a policy group to define a throughput ceiling for storage object workloads (QoS Max). You can apply the policy group when you create or modify the storage object.

### What you'll need

- You must be a cluster administrator to create a policy group.
- You must be a cluster administrator to apply a policy group to an SVM.

### About this task

- Beginning with ONTAP 9.4, you can use a *non-shared* QoS policy group to specify that the defined throughput ceiling applies to each member workload individually. Otherwise, the policy group is *shared*: the total throughput for the workloads assigned to the policy group cannot exceed the specified ceiling.

Set `-is-shared=false` for the `qos policy-group create` command to specify a non-shared policygroup.

- You can specify the throughput limit for the ceiling in IOPS, MB/s, or IOPS, MB/s. If you specify both IOPS and MB/s, whichever limit is reached first is enforced.

If you set a ceiling and a floor for the same workload, you can specify the throughput limit for the ceiling in IOPS only.

- A storage object that is subject to a QoS limit must be contained by the SVM to which the policy group belongs. Multiple policy groups can belong to the same SVM.
- You cannot assign a storage object to a policy group if its containing object or its child objects belong to the policy group.
- It is a QoS best practice to apply a policy group to the same type of storage objects.

### Steps

1. Create a policy group:

```
qos policy-group create -policy-group policy_group -vserver SVM -max-throughput number_of_iops|Mb/S|iops,Mb/S -is-shared true|false
```

For complete command syntax, see the man page. You can use the `qos policy-group modify` command to adjust throughput ceilings.

The following command creates the shared policy group `pg-vs1` with a maximum throughput of 5,000 IOPS:

```
cluster1::> qos policy-group create -policy-group pg-vs1 -vserver vs1 -max-throughput 5000iops -is-shared true
```

The following command creates the non-shared policy group `pg-vs3` with a maximum throughput of 100

IOPS and 400 Kb/S:

```
cluster1::> qos policy-group create -policy-group pg-vs3 -vserver vs3
-max-throughput 100iops,400KB/s -is-shared false
```

The following command creates the non-shared policy group pg-vs4 without a throughput limit:

```
cluster1::> qos policy-group create -policy-group pg-vs4 -vserver vs4
-is-shared false
```

## 2. Apply a policy group to an SVM, file, volume, or LUN:

```
storage_object create -vserver SVM -qos-policy-group policy_group
```

For complete command syntax, see the man pages. You can use the *storage\_object modify* command to apply a different policy group to the storage object.

The following command applies policy group pg-vs1 to SVM vs1:

```
cluster1::> vserver create -vserver vs1 -qos-policy-group pg-vs1
```

The following commands apply policy group pg-app to the volumes app1 and app2:

```
cluster1::> volume create -vserver vs2 -volume app1 -aggregate aggr1
-qos-policy-group pg-app
```

```
cluster1::> volume create -vserver vs2 -volume app2 -aggregate aggr1
-qos-policy-group pg-app
```

## 3. Monitor policy group performance:

```
qos statistics performance show
```

For complete command syntax, see the man page.

Monitor performance from the cluster. Do not use a tool on the host to monitor performance.

The following command shows policy group performance:

```
cluster1::> qos statistics performance show
Policy Group IOPS Throughput Latency

-total- 12316 47.76MB/s 1264.00us
pg_vs1 5008 19.56MB/s 2.45ms
_System-Best-Effort 62 13.36KB/s 4.13ms
_System-Background 30 0KB/s 0ms
```

#### 4. Monitor workload performance:

```
qos statistics workload performance show
```

For complete command syntax, see the man page.

Monitor performance from the cluster. Do not use a tool on the host to monitor performance.

The following command shows workload performance:

```
cluster1::> qos statistics workload performance show
Workload ID IOPS Throughput Latency

-total- - 12320 47.84MB/s 1215.00us
appl-wid7967 7967 7219 28.20MB/s 319.00us
vs1-wid12279 12279 5026 19.63MB/s 2.52ms
_USERSPACE_APPS 14 55 10.92KB/s 236.00us
_Scan_Backgro.. 5688 20 0KB/s 0ms
```

You can use the `qos statistics workload latency show` command to view detailed latency statistics for QoS workloads.

= Set a throughput floor with QoS

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

You can use the `min-throughput` field for a policy group to define a throughput floor for storage object workloads (QoS Min). You can apply the policy group when you create or modify the storage object. Beginning with ONTAP 9.8, you can specify the throughput floor in IOPS or MBps, or IOPS and MBps.

#### Before you begin

- You must be running ONTAP 9.2 or later. Throughput floors are available beginning with ONTAP 9.2.
- You must be a cluster administrator to create a policy group.
- Beginning in ONTAP 9.13.1, you can enforce throughput floors at the SVM level using an [adaptive policy group template](#). You cannot set an adaptive policy group template on an SVM with a QoS policy group.

## About this task

- Beginning with ONTAP 9.4, you can use a *non-shared* QoS policy group to specify that the defined throughput floor be applied to each member workload individually. This is the only condition in which a policy group for a throughput floor can be applied to multiple workloads.

Set `-is-shared=false` for the `qos policy-group create` command to specify a non-shared policy group.

- Throughput to a workload might fall below the specified floor if there is insufficient performance capacity (headroom) on the node or aggregate.
- A storage object that is subject to a QoS limit must be contained by the SVM to which the policy group belongs. Multiple policy groups can belong to the same SVM.
- It is a QoS best practice to apply a policy group to the same type of storage objects.
- A policy group that defines a throughput floor cannot be applied to an SVM.

## Steps

- Check for adequate performance capacity on the node or aggregate, as described in [permalink :identify-remaining-performance-capacity-task.html](#)[Identifying remaining performance capacity].
- Create a policy group:

```
qos policy-group create -policy group policy_group -vserver SVM -min-throughput qos_target -is-shared true|false
```

For complete command syntax, see the man page for your ONTAP release. You can use the `qos policy-group modify` command to adjust throughput floors.

The following command creates the shared policy group `pg-vs2` with a minimum throughput of 1,000 IOPS:

```
cluster1::> qos policy-group create -policy group pg-vs2 -vserver vs2 -min-throughput 1000iops -is-shared true
```

The following command creates the non-shared policy group `pg-vs4` without a throughput limit:

```
cluster1::> qos policy-group create -policy group pg-vs4 -vserver vs4 -is-shared false
```

- Apply a policy group to a volume or LUN:

```
storage_object create -vserver SVM -qos-policy-group policy_group
```

For complete command syntax, see the man pages. You can use the `_storage_object_modify` command to apply a different policy group to the storage object.

The following command applies policy group `pg-app2` to the volume `app2`:

```
cluster1::> volume create -vserver vs2 -volume app2 -aggregate aggr1
-qos-policy-group pg-app2
```

#### 4. Monitor policy group performance:

```
qos statistics performance show
```

For complete command syntax, see the man page.

Monitor performance from the cluster. Do not use a tool on the host to monitor performance.

The following command shows policy group performance:

```
cluster1::> qos statistics performance show
```

| Policy Group        | IOPS  | Throughput | Latency   |
|---------------------|-------|------------|-----------|
| -total-             | 12316 | 47.76MB/s  | 1264.00us |
| pg_app2             | 7216  | 28.19MB/s  | 420.00us  |
| _System-Best-Effort | 62    | 13.36KB/s  | 4.13ms    |
| _System-Background  | 30    | 0KB/s      | 0ms       |

#### 5. Monitor workload performance:

```
qos statistics workload performance show
```

For complete command syntax, see the man page.

Monitor performance from the cluster. Do not use a tool on the host to monitor performance.

The following command shows workload performance:

```
cluster1::> qos statistics workload performance show
```

| Workload        | ID    | IOPS  | Throughput | Latency   |
|-----------------|-------|-------|------------|-----------|
| -total-         | -     | 12320 | 47.84MB/s  | 1215.00us |
| app2-wid7967    | 7967  | 7219  | 28.20MB/s  | 319.00us  |
| vs1-wid12279    | 12279 | 5026  | 19.63MB/s  | 2.52ms    |
| _USERSPACE_APPS | 14    | 55    | 10.92KB/s  | 236.00us  |
| _Scan_Backgro.. | 5688  | 20    | 0KB/s      | 0ms       |

You can use the `qos statistics workload latency show` command to view detailed latency statistics for QoS workloads.

= Use adaptive QoS policy groups

You can use an *adaptive* QoS policy group to automatically scale a throughput ceiling or floor to volume size, maintaining the ratio of IOPS to TBs|GBs as the size of the volume changes. That is a significant advantage when you are managing hundreds or thousands of workloads in a large deployment.

### Before you begin

- You must be running ONTAP 9.3 or later. Adaptive QoS policy groups are available beginning with ONTAP 9.3.
- You must be a cluster administrator to create a policy group.

### About this task

A storage object can be a member of an adaptive policy group or a non-adaptive policy group, but not both. The SVM of the storage object and the policy must be the same. The storage object must be online.

Adaptive QoS policy groups are always non-shared: the defined throughput ceiling or floor applies to each member workload individually.

The ratio of throughput limits to storage object size is determined by the interaction of the following fields:

- `expected-iops` is the minimum expected IOPS per allocated TB|GB.

`expected-iops` is guaranteed on AFF platforms only. `expected-iops` is guaranteed for FabricPool only if the tiering policy is set to "none" and no blocks are in the cloud.  
`expected-iops` is guaranteed for volumes that are not in a SnapMirror Synchronous relationship.

- `peak-iops` is the maximum possible IOPS per allocated or used TB|GB.

- `expected-iops-allocation` specifies whether allocated space (the default) or used space is used for `expected-iops`.

`expected-iops-allocation` is available in ONTAP 9.5 and later. It is not supported in ONTAP 9.4 and earlier.

- `peak-iops-allocation` specifies whether allocated space or used space (the default) is used for `peak-iops`.

- `absolute-min-iops` is the absolute minimum number of IOPS. You can use this field with very small storage objects. It overrides both `peak-iops` and/or `expected-iops` when `absolute-min-iops` is greater than the calculated `expected-iops`.

For example, if you set `expected-iops` to 1,000 IOPS/TB, and the volume size is less than 1 GB, the calculated `expected-iops` will be a fractional IOP. The calculated `peak-iops` will be an even smaller fraction. You can avoid this by setting `absolute-min-iops` to a realistic value.

- `block-size` specifies the application I/O block size. The default is 32K. Valid values are 8K, 16K, 32K, 64K, ANY. ANY means that the block size is not enforced.

Three default adaptive QoS policy groups are available, as shown in the following table. You can apply these policy groups directly to a volume.

| Default policy group | Expected IOPS/TB | Peak IOPS/TB | Absolute Min IOPS |
|----------------------|------------------|--------------|-------------------|
| extreme              | 6,144            | 12,288       | 1000              |
| performance          | 2,048            | 4,096        | 500               |
| value                | 128              | 512          | 75                |

You cannot assign a storage object to a policy group if its containing object or its child objects belong to a policy group. The following table lists the restrictions.

| If you assign the...     | Then you cannot assign...                                       |
|--------------------------|-----------------------------------------------------------------|
| SVM to a policy group    | Any storage objects contained by the SVM to a policy group      |
| Volume to a policy group | The volume's containing SVM or any child LUNs to a policy group |
| LUN to a policy group    | The LUN's containing volume or SVM to a policy group            |
| File to a policy group   | The file's containing volume or SVM to a policy group           |

## Steps

1. Create an adaptive QoS policy group:

```
qos adaptive-policy-group create -policy group policy_group -vserver SVM
-expected-iops number_of_iops/TB|GB -peak-iops number_of_iops/TB|GB -expected-
-iops-allocation-space|used-space -peak-iops-allocation allocated-space|used-
-space -absolute-min-iops number_of_iops -block-size 8K|16K|32K|64K|ANY
```

For complete command syntax, see the man page.

-expected-iops-allocation and -block-size is available in ONTAP 9.5 and later.  
These options are not supported in ONTAP 9.4 and earlier.

The following command creates adaptive QoS policy group adpg-app1 with -expected-iops set to 300 IOPS/TB, -peak-iops set to 1,000 IOPS/TB, -peak-iops-allocation set to used-space, and -absolute-min-iops set to 50 IOPS:

```
cluster1::> qos adaptive-policy-group create -policy group adpg-app1
-vserver vs2 -expected-iops 300iops/tb -peak-iops 1000iops/TB -peak-iops-
-allocation used-space -absolute-min-iops 50iops
```

## 2. Apply an adaptive QoS policy group to a volume:

```
volume create -vserver SVM -volume volume -aggregate aggregate -size number_of
TB|GB -qos-adaptive-policy-group policy_group
```

For complete command syntax, see the man pages.

The following command applies adaptive QoS policy group adpg-app1 to volume app1:

```
cluster1::> volume create -vserver vs1 -volume app1 -aggregate aggr1
-size 2TB -qos-adaptive-policy-group adpg-app1
```

The following commands apply the default adaptive QoS policy group `extreme` to the new volume `app4` and to the existing volume `app5`. The throughput ceiling defined for the policy group applies to volumes `app4` and `app5` individually:

```
cluster1::> volume create -vserver vs4 -volume app4 -aggregate aggr4
-size 2TB -qos-adaptive-policy-group extreme
```

```
cluster1::> volume modify -vserver vs5 -volume app5 -qos-adaptive-policy
-group extreme
```

= Set an adaptive policy group template

:icons: font

:relative\_path: ./performance-admin/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest/..media/

Beginning in ONTAP 9.13.1, you can enforce throughput floors and ceilings at the SVM level using an adaptive policy group template.

### About this task

- The adaptive policy group template is a default policy `apg1`. The policy can be modified at any time. It can only be set with the CLI or ONTAP REST API and can only be applied to existing SVMs.
- The adaptive policy group template only impacts volumes created on or migrated to the SVM after you set the policy. Existing volumes on the SVM retain their existing status.

If you disable the adaptive policy group template, volumes on the SVM retain their existing policies. Only volumes subsequently created on or migrated to the SVM will be impacted by the disablement.

- You cannot set an adaptive policy group template on an SVM with a QoS policy group.
- Adaptive policy group templates are designed for AFF platforms. An adaptive policy group template can be set on other platforms, but the policy may not enforce a minimum throughput. Similarly, you can add an adaptive policy group template to an SVM in a FabricPool aggregate or in an aggregate that does not support a minimum throughput, however the throughput floor will not be enforced.
- If the SVM is in a MetroCluster configuration or an SnapMirror relationship, the adaptive policy group template will be enforced on the mirrored SVM.

## Steps

1. Modify the SVM to apply the adaptive policy group template:

```
vserver modify -qos-adaptive-policy-group-template apg1
```

2. Confirm the policy was set:

```
vserver show -fields qos-adaptive-policy-group
```

= Monitor cluster performance with Unified Manager

:toc: macro

:toplevels: 1

:hardbreaks:

:icons: font

:linkattrs:

:relative\_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest./media/

With Active IQ Unified Manager, you can maximize availability and maintain control of your NetApp AFF and FAS storage infrastructure for improved scalability, supportability, performance, and security.

Active IQ Unified Manager continuously monitors system health and send alerts, so your organization can free up IT staff resources. You can instantly view storage status from a single dashboard and quickly address issues through recommended actions.

Data management is simplified because you can discover, monitor, and receive notifications to proactively manage storage and quickly resolve issues. Admin efficiency is improved because you can monitor petabytes of data from a single dashboard and manage your data at scale.

With Active IQ Unified Manager, you can keep pace with fluctuating business demands, optimizing performance using performance data and advanced analytics. The reporting capabilities allow you to access standard reports or create custom operational reports to meet the specific needs of your business.

= Monitor cluster performance with Cloud Insights

:hardbreaks:

:icons: font

:linkattrs:

:relative\_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest./media/

NetApp Cloud Insights is a monitoring tool that gives you visibility into your complete infrastructure. With Cloud Insights, you can monitor, troubleshoot, and optimize all your resources including your public clouds and your private data centers.

== Cloud Insights comes in two editions

Cloud Insights Basic Edition is designed specifically to monitor and optimize your NetApp Data Fabric assets. It provides advanced analytics for the connections between all NetApp resources including HCI and All Flash FAS (AFF) within the environment free of charge.

Cloud Insights Standard Edition focuses not only on NetApp Data Fabric-enabled infrastructure components, but also on multi-vendor and multi-cloud environments. With its enriched capabilities, you can access support

for over 100 services and resources.

In today's world, with resources in play from your on-premises data centers to multiple public clouds, it's crucial to have the complete picture from the application itself to the backend disk of the storage array. The additional support for application monitoring (like Kafka, MongoDB, and Nginx) gives you the information and knowledge you need to operate at the optimal level of utilization as well as with the perfect risk buffer.

Both editions (Basic and Standard) can integrate with NetApp Active IQ Unified Manager. Customers who use Active IQ Unified Manager will be able to see join information inside the Cloud Insights user interface. Notifications posted on Active IQ Unified Manager will not be overlooked and can now be correlated to events in Cloud Insights. In other words, you get the best of both worlds.

**== Monitor, troubleshoot, and optimize all your resources**

Cloud Insights helps you significantly reduce the time to resolve issues and prevent them from impacting end users. It also helps you reduce cloud infrastructure costs. Your exposure to insider threats is reduced by protecting your data with actionable intelligence.

Cloud Insights gives you visibility to your entire hybrid infrastructure in one place—from the public cloud to your data center. You can instantly create relevant dashboards that can be customized to your specific needs. You can also create targeted and conditional alerts that are specific and relevant to your organization's needs.

Advanced anomaly detection helps you proactively fix issues before they arise. You can view resource contention and degradation automatically to quickly restore impacted workloads. Troubleshooting goes more quickly with the automatically built hierarchy of relationships between the different components in your stack.

You can identify unused or abandoned resources across your environment, which helps you discover opportunities to right-size the infrastructure and optimize your entire spend.

Cloud Insights visualizes your system topology to gain an understanding of your Kubernetes architecture. You can monitor the health of your Kubernetes clusters, including which nodes are in trouble, and zoom in when you see a problem.

Cloud Insights helps you protect organizational data from being misused by malicious or compromised users through advanced machine learning and anomaly detection that gives you actionable intelligence on insider threats.

Cloud Insights helps you to visualize Kubernetes metrics so you can fully understand the relations between your pods, nodes, and clusters. You're able to assess the health of a cluster or a working pod, as well as the load it is currently processing—enabling you to take command of your K8S cluster and to control both the health and the cost of your deployment.

**= File System Analytics**

**= File System Analytics overview**

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkattrs:

:relative\_path: ./

:imagesdir: /tmp/d20230517-16854-12t6yg9/source/.encryption-at-rest./media/

File System Analytics (FSA) was first introduced in ONTAP 9.8 to provide real-time visibility into file usage and storage capacity trends inside ONTAP FlexGroup or FlexVol

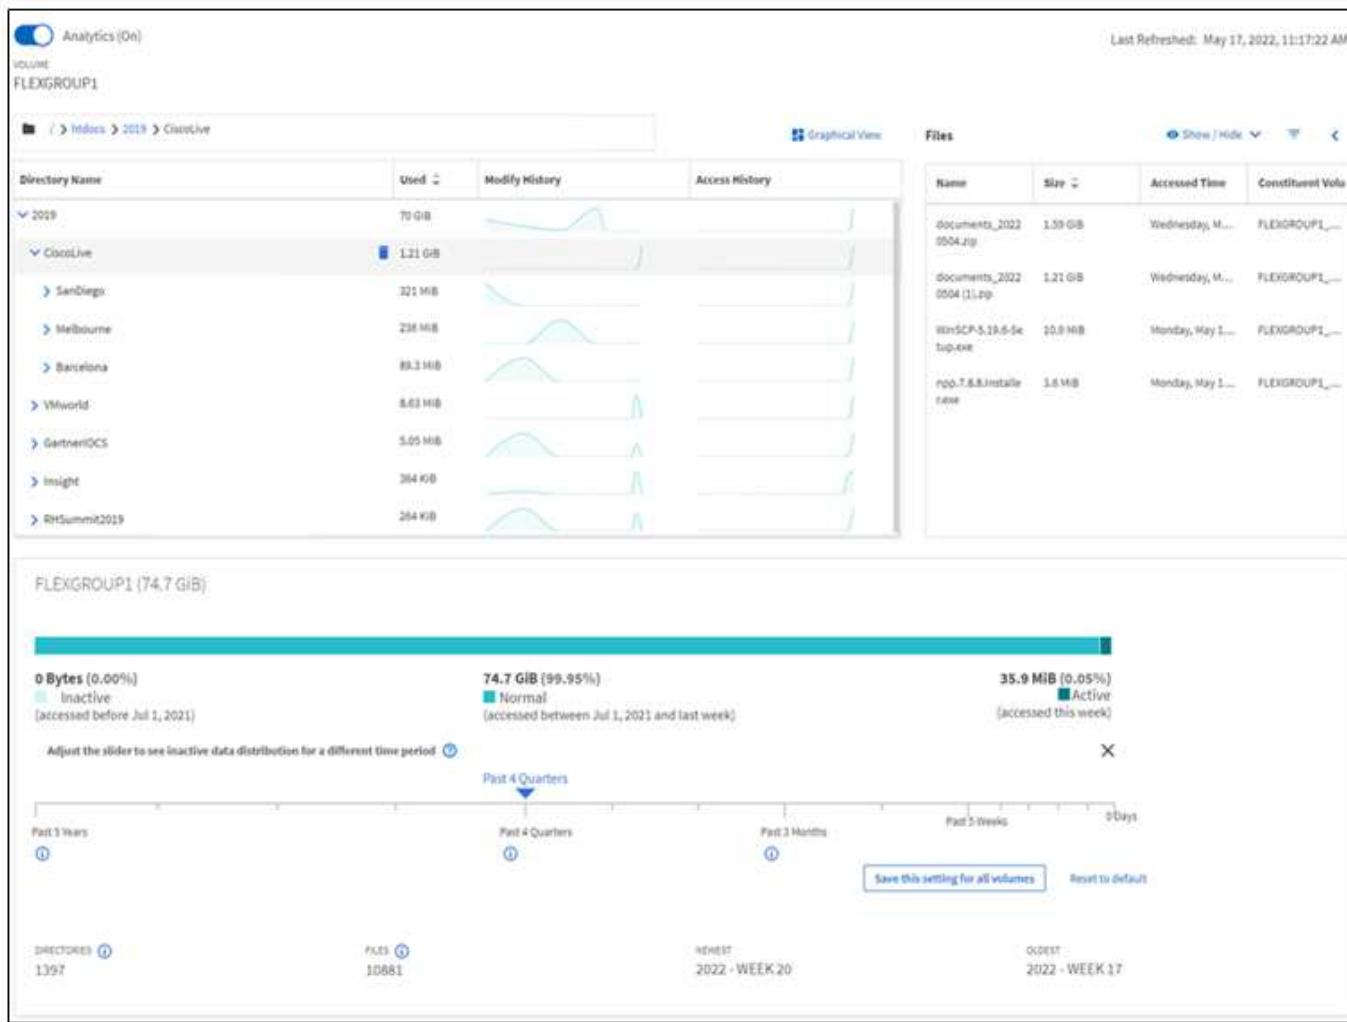

volumes. This native capability eliminates the need for external tools and provides key insights into how your storage is utilized and whether there are opportunities to optimize the storage for your business needs.

With FSA, you have visibility at all levels of a volume's file system hierarchy in NAS. For example, you can gain usage and capacity insights at the Storage VM (SVM), volume, directory, and file levels. You can use FSA to answer questions like:

- What is filling up my storage, and are there any large files I can move to another storage location?
- Which are my most active volumes, directories, and files? Is my storage performance optimized for the needs of my users?
- How much data was added in the last month?
- Who are my most active or least active storage users?
- How much inactive or dormant data is on my primary storage? Can I move that data to a lower cost cold tier?
- Will my planned quality-of-service changes negatively impact access to critical, frequently accessed files?

File System Analytics is integrated into ONTAP System Manager. Views within System Manager provide:

- Real-time visibility for effective data management and operation
- Real-time data collection and aggregation
- Subdirectory and file sizes and counts, together with associated performance profiles
- File age histograms for modify and access histories

## == Supported volume types

File System Analytics is designed to provide visibility on volumes with active NAS data, with the exception of FlexCache caches and SnapMirror destination volumes.

## == File System Analytics feature availability

Each ONTAP release expands the scope of File System Analytics.

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/
```

To collect and display usage data such as capacity analytics, you need to enable File System Analytics on a volume.

## About this task

- Beginning with ONTAP 9.8, you can enable File System Analytics on a new or existing volume. If you upgrade a system to ONTAP 9.8 or later, ensure that all upgrade processes have completed before you enable File System Analytics.
- Depending on the size and contents of the volume, enabling analytics may take time while ONTAP processes existing data in the volume. System Manager displays progress and presents analytics data when complete. If you need more precise information about initialization progress, you can use the ONTAP CLI command `volume analytics show`.

## About this task

Depending on the size and contents of the volume, enabling analytics may take time while ONTAP processes existing data in the volume. System Manager displays progress and presents analytics data when complete. If you need more precise information about initialization progress, you can use the ONTAP CLI command `volume analytics show`.

For additional considerations related to the initialization scan, see [Scan considerations](#).

## Steps

You can enable File System Analytics with ONTAP System Manager or the CLI.

| In ONTAP 9.8 and 9.9.1                                                                                                                                                                                                      | Beginning in ONTAP 9.10.1                                                                                                                                                                                                                                                |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ol style="list-style-type: none"> <li>Select <b>Storage &gt; Volumes</b>.</li> <li>Select the desired volume, then select <b>Explorer</b>.</li> <li>Select <b>Enable Analytics</b> or <b>Disable Analytics</b>.</li> </ol> | <ol style="list-style-type: none"> <li>Select <b>Storage &gt; Volumes</b>.</li> <li>Select the desired volume. From the individual volume menu, select <b>File System &gt; Explorer</b>.</li> <li>Select <b>Enable Analytics</b> or <b>Disable Analytics</b>.</li> </ol> |

## Enable File System Analytics with the CLI

- Run the following command:

```
volume analytics on -vserver svm_name -volume volume_name [-foreground {true|false}]
```

By default, the command runs in the foreground; ONTAP displays progress and presents analytics data when complete. If you need more precise information, you can run the command in the background by using the `-foreground false` option and then use the `volume analytics show` command to display initialization progress in the CLI.

- After successfully enabling File System Analytics, use System Manager or the ONTAP REST API to display the analytic data.

### == Modify default File System Analytics settings

Beginning in ONTAP 9.13.1, you can modify SVM or clusters settings to enable File System Analytics by default on new volumes.

If you are using System Manager, you can modify the storage VM or cluster settings to enable capacity analytics and Activity Tracking at volume creation by default. Default enablement only applies to volumes created after you modify the settings, not existing volumes.

## Modify File System Analytics settings on a cluster

- In System Manager, navigate to **Cluster settings**.

2. In **Cluster settings**, review the File System Settings tab. To modify the settings, select the  icon.
3. In the **Activity Tracking** field, enter the names of the SVMs to enable Activity Tracking for by default. Leaving the field blank will leave Activity Tracking disabled on all SVMs.  
Uncheck the **Enable on new storage VMs** box to disable Activity Tracking by default on new storage VMs.
4. In the **Analytics** field, enter the names of the storage VMs you want capacity analytics enabled for by default. Leaving the field blank will leave capacity analytics disabled on all SVMs.  
Uncheck the **Enable on new storage VMs** box to disable capacity analytics by default on new storage VMs.
5. Select **Save**.

#### Modify File System Analytics settings on an SVM

1. Select the SVM you want to modify then **Storage VM settings**.
2. In the **File System Analytics** card, use the toggles to enable or disable Activity Tracking and capacity analytics for all new volumes on the storage VM.

You can configure the storage VM to enable File System Analytics by default on new volumes using the ONTAP CLI.

#### Enable File System Analytics by default on an SVM

1. Modify the SVM to enable capacity analytics and Activity Tracking by default on all newly created volumes:  
`vserver modify -vserver svm_name -auto-enable-activity-tracking true -auto-enable-analytics true`

```
= View file system activity
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkattrs:
:relative_path: /
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest./media/
```

After File System Analytics (FSA) is enabled, you can view the root directory contents of a selected volume sorted by the space used in each subtree.

Select any file system object to browse the file system and to display detailed information about each object in a directory. Information about directories can also be displayed graphically. Over time, historical data is displayed for each subtree. Space used is not sorted if there are more than 3000 directories.

## == Explorer

The File System Analytics **Explorer** screen consists of three areas:

- Tree view of directories and subdirectories; expandable list showing name, size, modify history, and access history.
- Files; showing name, size, and accessed time for the object selected in the directory list.
- Active and inactive data comparison for the object selected in the directory list.

Beginning with ONTAP 9.9.1, you can customize the range to be reported. The default value is one year. Based on these customizations, you can take corrective actions, such as moving volumes and modifying the tiering policy.

Accessed time is shown by default. However, if the volume default has been altered from the CLI (by setting the `-atime-update` option to `false` with the `volume modify` command), then only last modified time is shown. For example:

- The tree view will not display the **access history**.
- The files view will be altered.
- The active/inactive data view will be based on modified time (`mtime`).

Using these displays, you can examine the following:

- File system locations consuming the most space
- Detailed information about a directory tree, including file and subdirectory count within directories and subdirectories
- File system locations that contain old data (for example, scratch, temp, or log trees)

Keep the following points in mind when interpreting FSA output:

- FSA show where and when your data is in use, not how much data is being processed. For example, large space consumption by recently accessed or modified files does not necessarily indicate high system processing loads.

- The way that the **Volume Explorer** tab calculates space consumption for FSA might differ from other tools. In particular, there could be significant differences compared to the consumption reported in the **Volume Overview** if the volume has storage efficiency features enabled. This is because the **Volume Explorer** tab does not include efficiency savings.
- Due to space limitations in the directory display, it is not possible to view a directory depth greater than 8 levels in the *List View*. To view directories more than 8 levels deep, you must switch to *Graphical View*, locate the desired directory, then switch back to *List View*. This will allow additional screen space in the display.

## Steps

- View the root directory contents of a selected volume:

| In ONTAP 9.8 and 9.9.1                                                                      | Beginning in ONTAP 9.10.1                                                                                                                  |
|---------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Click <b>Storage &gt; Volumes</b> , select the desired volume, then click <b>Explorer</b> . | Select <b>Storage &gt; Volumes</b> , select the desired volume. From the individual volume menu, select <b>File System &gt; Explorer</b> . |

= Enable Activity Tracking

:icons: font

:relative\_path: ./file-system-analytics/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

Beginning with ONTAP 9.10.1, File System Analytics includes an Activity Tracking feature that allows you to identify hot objects and download the data as a CSV file. Beginning with ONTAP 9.11.1, Activity Tracking is expanded to the SVM scope. Also beginning in ONTAP 9.11.1, System Manager features a timeline for Activity Tracking, allowing you to look through up to five minutes of Activity Tracking data.

Activity Tracking enables monitoring in four categories:

- Directories
- Files
- Clients
- Users

For each category monitored, Activity Tracking will display read IOPs, write IOPs, read throughputs, and write throughputs. Queries on Activity Tracking refresh every 10 to 15 seconds pertaining to hot spots seen in the system over the previous five-second interval.

Activity tracking information is approximate, and the accuracy of the data depends on the distribution of the incoming I/O traffic.

When viewing Activity Tracking in System Manager at the volume level, only the menu of the expanded volume will actively refresh. If the view of any volumes are collapsed, they will not refresh until the volume display is expanded. You can stop the refreshes with the **Pause Refresh** button. Activity data can be downloaded in a CSV format that will display all the point-in-time data captured for the selected volume.

With the timeline feature available beginning in ONTAP 9.11.1, you can keep a record of hotspot activity on a volume or SVM, continuously updating approximately every five seconds and retaining the previous five minutes of data. Timeline data is only retained for fields that are visible area of the page. If you

collapse a tracking category or scroll so the timeline is out of view, the timeline will stop collecting data. By default, timelines are disabled and will automatically be disabled when you navigate away from the Activity tab.

**== Enable Activity Tracking for a single volume**

You can enable Activity Tracking with ONTAP System Manager or the CLI.

#### About this task

If you use RBAC with the ONTAP REST API or System Manager, you will need to create custom roles to manage access to Activity Tracking. See [Role-based access control](#) for this process.

#### Steps

1. Select **Storage > Volumes**. Select the desired volume. From the individual volume menu, select File System and then select the Activity tab.
2. Ensure **Activity Tracking** is turned on to view individual reports on top directories, files, clients, and users.
3. To analyze data in greater depth without refreshes, select **Pause Refresh**. You can download the data to have a CSV record of the report as well.

#### Steps

1. Enable Activity Tracking:

```
volume activity-tracking on -vsserver svm_name -volume volume_name
```

2. Check if the Activity Tracking state for a volume is on or off with the command:

```
volume activity-tracking show -vsserver svm_name -volume volume_name -state
```

3. Once enabled, use ONTAP System Manager or the ONTAP REST API to display Activity Tracking data.

**== Enable Activity Tracking for multiple volumes**

You can enable Activity Tracking for multiple volumes at once with System Manager.

#### About this task

If you use RBAC with the ONTAP REST API or System Manager, you will need to create custom roles to manage access to Activity Tracking. See [Role-based access control](#) for this process.

#### Enable for specific volumes

1. Select **Storage > Volumes**. Select the desired volume. From the individual volume menu, select File System and then select the Activity tab.
2. Select the volumes that you want to enable Activity Tracking on. At the top of the volume list, select the **More Options** button. Select **Enable Activity Tracking**.
3. To view Activity Tracking at the SVM level, select the specific SVM you would like to view from **Storage > Volumes**. Navigate to the File System tab then Activity and you will see data for the volumes that have Activity Tracking enabled.

#### Enable for all volumes

1. Select **Storage > Volumes**. Select an SVM from the menu.

2. Navigate to the **File System** tab, choose the **More** tab to enable Activity Tracking on all volumes in the SVM.

Beginning in ONTAP 9.13.1, you can enable Activity Tracking for multiple volumes using the ONTAP CLI.

## Steps

1. Enable Activity Tracking:

```
volume activity-tracking on -vserver svm_name -volume [*|!volume_names]
```

Use \* to enable Activity Tracking for all volumes on the specified storage VM.

Use ! followed by volume names to enable Activity Tracking for all volumes on the SVM except the named volumes.

2. Confirm the operation succeeded:

```
volume show -fields activity-tracking-state
```

3. Once enabled, use ONTAP System Manager or the ONTAP REST API to display Activity Tracking data.

```
= Enable usage analytics
:icons: font
:relative_path: ./file-system-analytics/
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/./media/
```

Tracking directories by size enables you to capture important data about the directories in a volume using the most space. Tracking directories by size is available beginning in ONTAP 9.12.1 and provides:

- The total number of directories in the volume
- The total number of files in the volume
- A bar chart identifying the largest directories in the volume by size in descending order

Tracking for large directories will refresh every 15 minutes. File System Analytics limits reporting of large directories to the 25 directories consuming the most space.

You can monitor the most recent refresh by checking the **Last Refreshed** timestamp at the top of the page. You can additionally download tracking data to an Excel workbook with the **Download** button. The download operation will run in the background and present the most recently reported information for the selected volume.

If the scan returns without any results, ensure the volume is online. Events such as SnapRestore will cause File System Analytics to rebuild its list of large directories.

## Steps

1. Select **Storage > Volumes**. Select the desired volume.
2. From the individual volume menu, select **File System**. Then select the **Usage** tab.
3. Toggle the **Analytics** switch to enable usage analytics.
4. System Manager will display a bar graph identifying the directories with the largest size in descending order.

ONTAP might display partial data or no data at all while the list of top directories is being collected. The progress of the scan can be in the **Usage** tab that displays during the scan.

Gain more insights about any directory by selecting the directory to go to the the Explorer tab. For more information about the **Explorer** tab, refer to [View activity on a file system](#).

```
= Take corrective action based on analytics
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ../
:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/./media/
```

Beginning with ONTAP 9.9.1, you can take corrective actions based on current data and desired outcomes directly from the File System Analytics displays.

When analytics are enabled, you can take the following actions:

- Delete directories and files

In the Explorer display, you can select directories or individual files to delete. Directories are deleted with low-latency fast directory delete functionality. (Fast directory delete is also available beginning in ONTAP 9.9.1 without analytics enabled.)

- Assign media cost in storage tiers to compare costs of inactive data storage locations

Media cost is a value that you assign based on your evaluation of storage costs, represented as your choice of currency per GB. When set, System Manager uses the assigned media cost to project estimated savings when you move volumes.

The media cost you set is not persistent; it can only be set for a single browser session.

- Move volumes to reduce storage costs

Based on analytics displays and media cost comparisons, you can move volumes to less expensive storage in local tiers.

Only one volume at a time can be compared and moved.

| To perform this action...    | Take these steps...                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Delete directories or files  | <ol style="list-style-type: none"><li>1. Click <b>Storage &gt; Volumes</b>, then click <b>Explorer</b>.<br/>When you hover over a file or folder, the option to delete appears. You can only delete one object at a time.<br/><br/> When directories and files are deleted, the new storage capacity values are not displayed immediately.</li></ol> |
| Enable media cost comparison | <ol style="list-style-type: none"><li>1. Click <b>Storage &gt; Tiers</b>, then click <b>Set Media Cost</b> in the desired local tier (aggregate) tiles.<br/>Be sure to select active and inactive tiers to enable comparison.</li><li>2. Enter a currency type and amount.<br/>When you enter or change the media cost, the change is made in all media types.</li></ol>                                                                |

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Move volumes to a less expensive tier | <ol style="list-style-type: none"> <li>1. After enabling media cost display, click <b>Storage &gt; Tiers</b>, then click <b>Volumes</b>.</li> <li>2. To compare destination options for a volume, click  for the volume, then click <b>Move</b>.</li> <li>3. In the <b>Select Destination Local Tier</b> display, select destination tiers to display the estimated cost difference.</li> <li>4. After comparing options, select the desired tier and click <b>Move</b>.</li> </ol> |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

= Role-based access control with File System Analytics

:icons: font

:relative\_path: ./file-system-analytics/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest../media/

Beginning in ONTAP 9.12.1, ONTAP includes a predefined role-based access control (RBAC) role called `admin-no-fsa`. The `admin-no-fsa` role grants administrator-level privileges but prevents the user from performing operations related to the `files` endpoint (i.e. File System Analytics) in the ONTAP CLI, REST API, and in System Manager.

For more information on the `admin-no-fsa` role, refer to [Predefined roles for cluster administrators](#).

If you are using a version of ONTAP released prior to ONTAP 9.12.1, you will need to create a dedicated role to control access to File System Analytics. In versions of ONTAP prior to ONTAP 9.12.1, you must configure RBAC permissions through the ONTAP CLI or ONTAP REST API.

Beginning in ONTAP 9.12.1, you can configure RBAC permissions for File System Analytics using System Manager.

## Steps

1. Select **Cluster > Settings**. Under **Security**, navigate to **Users and Roles** and select .
2. Under **Roles**, select  **Add**.
3. Provide a name for the role. Under **Role Attributes**, configure the access or restrictions for the user role by providing the appropriate [API endpoints](#). See the table below for primary paths and secondary paths to configure File System Analytics access or restrictions.

| Restriction                          | Primary Path         | Secondary Path                                                                                                                                                                                   |
|--------------------------------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Activity Tracking on volumes         | /api/storage/volumes | <ul style="list-style-type: none"> <li>• /:uuid/top-metrics/directories</li> <li>• /:uuid/top-metrics/files</li> <li>• /:uuid/top-metrics/clients</li> <li>• /:uuid/top-metrics/users</li> </ul> |
| Activity Tracking on SVMs            | /api/svm/svms        | <ul style="list-style-type: none"> <li>• /:uuid/top-metrics/directories</li> <li>• /:uuid/top-metrics/files</li> <li>• /:uuid/top-metrics/clients</li> <li>• /:uuid/top-metrics/users</li> </ul> |
| All File System Analytics operations | /api/storage/volumes | /:uuid/files                                                                                                                                                                                     |

You can use /\* instead of an UUID to set the policy for all volumes or SVMs at the endpoint.

Choose the access privileges for each endpoint.

4. Select **Save**.
5. To assign the role to a user or users, see [Control administrator access](#).

If you are using a version of ONTAP released prior to ONTAP 9.12.1, use the ONTAP CLI to create a custom-role.

### Steps

1. Create a default role to have access to all features.

This needs to be done before creating the restrictive role to ensure the role is only restrictive on the Activity Tracking:

```
security login role create -cmddirname DEFAULT -access all -role storageAdmin
```

2. Create the restrictive role:

```
security login role create -cmddirname "volume file show-disk-usage" -access none -role storageAdmin
```

3. Authorize roles to access the SVM's web services:

- rest for REST API calls

- security for password protection
- sysmgr for System Manager access

```
vserver services web access create -vserver svm-name -name_ -name rest -role storageAdmin
```

```
vserver services web access create -vserver svm-name -name security -role storageAdmin
```

```
vserver services web access create -vserver svm-name -name sysmgr -role storageAdmin
```

#### 4. Create a user.

You must issue a distinct create command for each application you would like to apply to the user. Calling create multiple times on the same user simply applies all the applications to that one user and does not create a new user each time. The http parameter for application type applies for the ONTAP REST API and System Manager.

```
security login create -user-or-group-name storageUser -authentication-method password -application http -role storageAdmin
```

#### 5. With the new user credentials, you can now log in to System Manager or use the ONTAP REST API to access File Systems Analytics data.

## More information

- [Predefined roles for cluster administrators](#)
- [Control administrator access with System Manager](#)
- [Learn more about RBAC roles and the ONTAP REST API](#)

= Considerations for File System Analytics

:icons: font

:relative\_path: ./file-system-analytics/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You should be aware of certain usage limits and potential performance impacts associated with implementing File System Analytics.

== SVM-protected relationships

If you have enabled File System Analytics on volumes whose containing SVM is in a protection relationship, the analytics data is not replicated to the destination SVM. If the source SVM must be resynchronized in a recovery operation, you must manually reenable analytics on desired volumes after recovery.

== Performance considerations

In some cases, enabling File System Analytics could negatively impact performance during the initial metadata collection. This is most typically seen on systems that are at maximum utilization. To avoid enabling analytics on such systems, you can use ONTAP System Manager performance monitoring tools.

If you experience a notable increase in latency, refer to the Knowledge Base article [High or fluctuating latency after turning on NetApp ONTAP File System Analytics](#).

== Scan considerations

When you enable capacity analytics, ONTAP conducts an initialization scan. The scan accesses metadata for all files in volumes for which capacity analytics is enabled. No file data is read during the scan.

After the scan completes, File System Analytics is continuously updated in real time as the filesystem changes without the need to run the scan again.

The time required for the scan is proportional to the number of directories and files on the volume. Because the scan collects metadata, file size does not impact the scan time.

For more information about the initialization scan, see [TR-4867: Best practice guidelines for File System Analytics](#).

== Best practices

You should start the scan on volumes that do not share aggregates. You can see which aggregates are currently hosting which volumes using the command:

```
volume show -volume comma-separated-list_of_volumes -fields aggr-list
```

While the scan runs, volumes continue to serve client traffic. It's recommended you start the scan during periods where you anticipate lower client traffic.

If client traffic increases, it will consume system resources and cause the scan to take longer.

Beginning in ONTAP 9.12.1, you can pause data collection in System Manager and with the ONTAP CLI.

- If you are using the ONTAP CLI:

- You can pause data collection with the command: `volume analytics initialization pause -vserver svm_name -volume volume_name`
- Once client traffic has slowed, you can resume data collection with the command: `volume analytics initialization resume -vserver svm_name -volume volume_name`

- If you are using System Manager, in the **Explorer** view of the volume menu, you use the **Pause Data Collection** and **Resume Data Collection** buttons to manage the scan.

= EMS configuration

= EMS configuration overview

:icons: font

:relative\_path: ./error-messages/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./encryption-at-rest/..media/

You can configure ONTAP 9 to send important EMS (Event Management System) event notifications directly to an email address, syslog server, Simple Management Network Protocol (SNMP) traphost, or webhook application so that you are immediately notified of system issues that require prompt attention.

Because important event notifications are not enabled by default, you need to configure the EMS to send notifications to either an email address, a syslog server, an SNMP traphost, or webhook application.

Review release-specific versions of the [ONTAP 9 EMS Reference](#).

If your EMS event mapping uses deprecated ONTAP command sets (such as event destination, event route), it's recommended that you update your mapping. [Learn how to update your EMS mapping from deprecated ONTAP commands](#).

= Configure EMS event notifications and filters with System Manager

You can use System Manager to configure how the Event Management System (EMS) delivers event notifications so that you can be notified of system issues that require your prompt attention.

| ONTAP version          | With System Manager, you can...                                                                                                             |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| ONTAP 9.12.1 and later | Specify Transport Layer Security (TLS) protocol when sending events to remote syslog servers.                                               |
| ONTAP 9.10.1 and later | Configure email addresses, syslog servers, and webhook applications, as well as SNMP traphosts.                                             |
| ONTAP 9.7 to 9.10.0    | Configure only SNMP traphosts. You can configure other EMS destination with the ONTAP CLI. See <a href="#">EMS configuration overview</a> . |

You can perform the following procedures:

- [add-ems-destination]
- [create-ems-filter]
- [edit-ems-destination]
- [edit-ems-filter]
- [delete-ems-destination]
- [delete-ems-filter]

#### Related information

- [ONTAP EMS Reference](#)
- [Using the CLI to configure SNMP traphosts to receive event notifications](#)

== Add an EMS event notification destination

You can use System Manager to specify to where you want EMS messages sent.

Beginning with ONTAP 9.12.1, EMS events can be sent to a designated port on a remote syslog server via the Transport Layer Security (TLS) protocol. For details, see the `event_notification destination create` man page.

#### Steps

1. Click **Cluster > Settings**.
2. In the **Notifications Management** section, click  , then click **View Event Destinations**.
3. On the **Notification Management** page, select the **Events Destinations** tab.
4. Click  **Add**.
5. Specify a name, an EMS destination type, and filters.

If needed, you can add a new filter. Click **Add a New Event Filter**.

6. Depending on the EMS destination type you selected, specify the following:

| To configure...                  | Specify or select...                                                                                                           |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| SNMP traphost                    | <ul style="list-style-type: none"><li>• Traphost name</li></ul>                                                                |
| Email<br>(Beginning with 9.10.1) | <ul style="list-style-type: none"><li>• Destination email address</li><li>• Mail server</li><li>• From email address</li></ul> |

|                                              |                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Syslog server<br><br>(Beginning with 9.10.1) | <ul style="list-style-type: none"> <li>• Host name or IP address of the server</li> <li>• Syslog port (beginning with 9.12.1)</li> <li>• Syslog transport (beginning with 9.12.1)</li> </ul> <p>Selecting <b>TCP Encrypted</b> enables the Transport Layer Security (TLS) protocol. If no value is entered for <b>Syslog port</b>, a default is used based on the <b>Syslog transport</b> selection.</p> |
| Webhook<br><br>(Beginning with 9.10.1)       | <ul style="list-style-type: none"> <li>• Webhook URL</li> <li>• Client authentication (select this option to specify a client certificate)</li> </ul>                                                                                                                                                                                                                                                    |

## == Create a new EMS event notification filter

Beginning with ONTAP 9.10.1, you can use System Manager to define new customized filters that specify the rules for handling EMS notifications.

### Steps

1. Click **Cluster > Settings**.
2. In the **Notifications Management** section, click  , then click **View Event Destinations**.
3. On the **Notification Management** page, select the **Event Filters** tab.
4. Click  .
5. Specify a name, and select whether you want to copy rules from an existing event filter or add new rules.
6. Depending on your choice, perform the following steps:

| If you choose....                            | Then, perform these steps...                                                                                                                                                                                                                                            |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Copy rules from existing event filter</b> | <ol style="list-style-type: none"> <li>1. Select an existing event filter.</li> <li>2. Modify the existing rules.</li> <li>3. Add other rules, if needed, by clicking .</li> </ol> |
| <b>Add new rules</b>                         | Specify the type, name pattern, severities, and SNMP trap type for each new rule.                                                                                                                                                                                       |

## == Edit an EMS event notification destination

Beginning with ONTAP 9.10.1, you can use System Manager to change the event notification destination information.

### Steps

1. Click **Cluster > Settings**.
2. In the **Notifications Management** section, click  , then click **View Event Destinations**.
3. On the **Notifications Management** page, select the **Events Destinations** tab.

4. Next to the name of the event destination, click , then click **Edit**.
5. Modify the event destination information, then click **Save**.

== Edit an EMS event notification filter

Beginning with ONTAP 9.10.1, you can use System Manager to modify customized filters to change how event notifications are handled.

You cannot modify system-defined filters.

## Steps

1. Click **Cluster > Settings**.
2. In the **Notifications Management** section, click , then click **View Event Destinations**.
3. On the **Notification Management** page, select the **Event Filters** tab.
4. Next to the name of the event filter, click , then click **Edit**.
5. Modify the event filter information, then click **Save**.

== Delete an EMS event notification destination

Beginning with ONTAP 9.10.1, you can use System Manager to delete an EMS event notification destination.

You cannot delete SNMP destinations.

## Steps

1. Click **Cluster > Settings**.
2. In the **Notifications Management** section, click , then click **View Event Destinations**.
3. On the **Notification Management** page, select the **Events Destinations** tab.
4. Next to the name of the event destination, click , then click **Delete**.

== Delete an EMS event notification filter

Beginning with ONTAP 9.10.1, you can use System Manager to delete customized filters.

You cannot delete system-defined filters.

## Steps

1. Click **Cluster > Settings**.
2. In the **Notifications Management** section, click , then click **View Event Destinations**.
3. On the **Notification Management** page, select the **Event Filters** tab.
4. Next to the name of the event filter, click , then click **Delete**.

= Configure EMS event notifications with the CLI

= EMS configuration workflow

:icons: font

:relative\_path: ./error-messages/

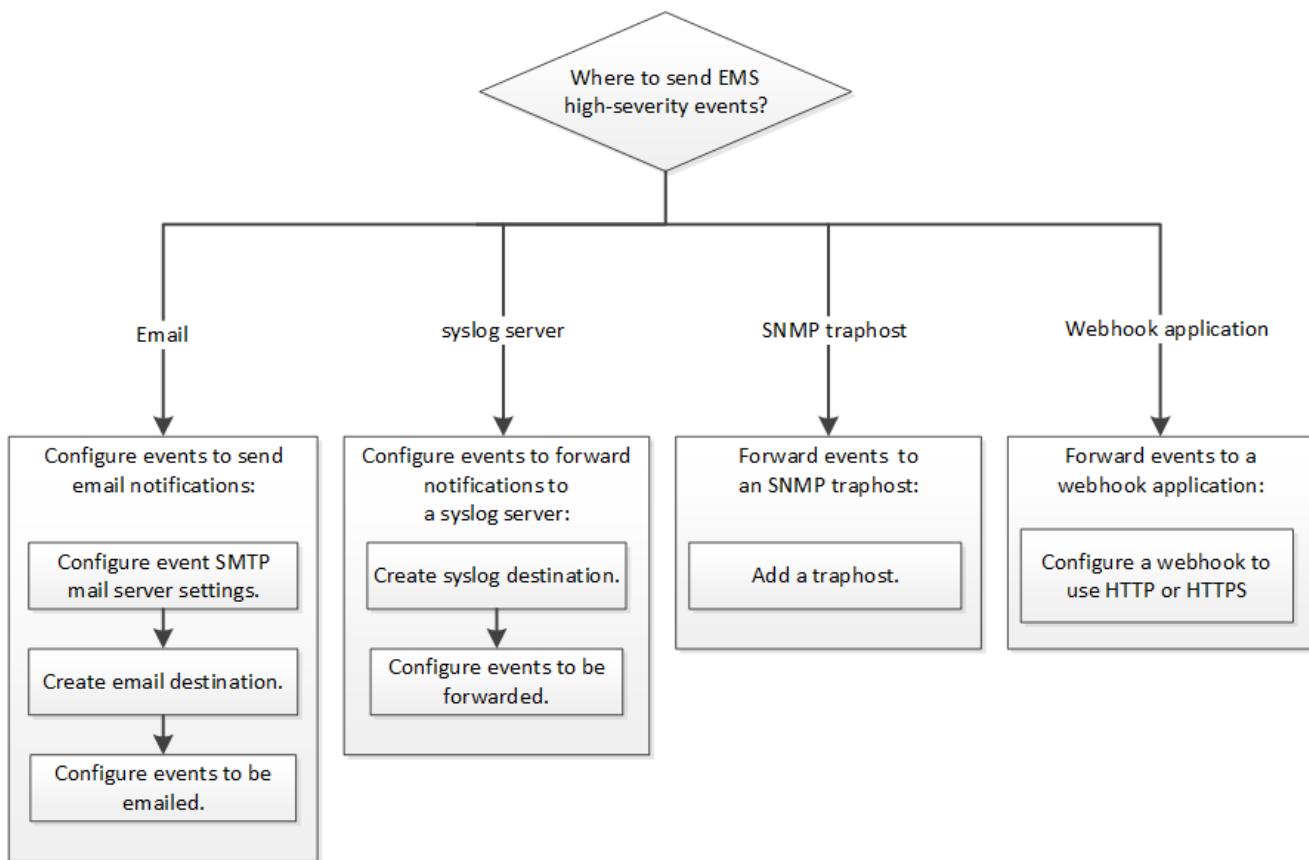

You must configure important EMS event notifications to be sent either as email, forwarded to a syslog server, forwarded to an SNMP traphost, or forwarded to a webhook application. This helps you to avoid system disruptions by taking corrective actions in a timely manner.

### About this task

If your environment already contains a syslog server for aggregating the logged events from other systems, such as servers and applications, then it is easier to use that syslog server also for important event notifications from storage systems.

If your environment does not already contain a syslog server, then it is easier to use email for important event notifications.

If you already forward event notifications to an SNMP traphost, then you might want to monitor that traphost for important events.

### Choices

- Set EMS to send event notifications.

| If you want...                                                    | Refer to this...                                                           |
|-------------------------------------------------------------------|----------------------------------------------------------------------------|
| The EMS to send important event notifications to an email address | <a href="#">Configure important EMS events to send email notifications</a> |

|                                                                             |                                                                                                  |
|-----------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| The EMS to forward important event notifications to a syslog server         | <a href="#">Configure important EMS events to forward notifications to a syslog server</a>       |
| If you want the EMS to forward event notifications to an SNMP traphost      | <a href="#">Configure SNMP traphosts to receive event notifications</a>                          |
| If you want the EMS to forward event notifications to a webhook application | <a href="#">Configure important EMS events to forward notifications to a webhook application</a> |

= Configure important EMS events to send email notifications

:icons: font

:relative\_path: ./error-messages/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./error-messages/./media/

To receive email notifications of the most important events, you must configure the EMS to send email messages for events that signal important activity.

### What you'll need

DNS must be configured on the cluster to resolve the email addresses.

### About this task

You can perform this task any time the cluster is running by entering the commands on the ONTAP command line.

### Steps

1. Configure the event SMTP mail server settings:

```
event config modify -mail-server mailhost.your_domain -mail-from
cluster_admin@your_domain
```

2. Create an email destination for event notifications:

```
event notification destination create -name storage-admins -email
your_email@your_domain
```

3. Configure the important events to send email notifications:

```
event notification create -filter-name important-events -destinations
storage-admins
```

= Configuring important EMS events to forward notifications to a syslog server

:icons: font

:relative\_path: ./error-messages/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./error-messages/./media/

To log notifications of the most severe events on a syslog server, you must configure the EMS to forward notifications for events that signal important activity.

### What you'll need

DNS must be configured on the cluster to resolve the syslog server name.

## About this task

If your environment does not already contain a syslog server for event notifications, you must first create one. If your environment already contains a syslog server for logging events from other systems, then you might want to use that one for important event notifications.

You can perform this task any time the cluster is running by entering the commands on the ONTAP CLI.

Beginning with ONTAP 9.12.1, EMS events can be sent to a designated port on a remote syslog server via the Transport Layer Security (TLS) protocol. Two new parameters are available:

### **tcp-encrypted**

When `tcp-encrypted` is specified for the `syslog-transport`, ONTAP verifies the identity of the destination host by validating its certificate. The default value is `udp-unencrypted`.

### **syslog-port**

The default value `syslog-port` parameter depends on the setting for the `syslog-transport` parameter. If `syslog-transport` is set to `tcp-encrypted`, `syslog-port` has the default value 6514.

For details, see the `event notification destination create` man page.

## Steps

1. Create a syslog server destination for important events:

```
event notification destination create -name syslog-ems -syslog syslog-server-address -syslog-transport {udp-unencrypted|tcp-unencrypted|tcp-encrypted}
```

Beginning with ONTAP 9.12.1, the following values can be specified for `syslog-transport`:

- `udp-unencrypted` - User Datagram Protocol with no security
- `tcp-unencrypted` - Transmission Control Protocol with no security
- `tcp-encrypted` - Transmission Control Protocol with Transport Layer Security (TLS)

The default protocol is `udp-unencrypted`.

2. Configure the important events to forward notifications to the syslog server:

```
event notification create -filter-name important-events -destinations syslog-ems
```

= Configure SNMP traphosts to receive event notifications

:icons: font

:relative\_path: ./error-messages/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./error-messages./media/

To receive event notifications on an SNMP traphost, you must configure a traphost.

## What you'll need

- SNMP and SNMP traps must be enabled on the cluster.

SNMP and SNMP traps are enabled by default.

- DNS must be configured on the cluster to resolve the traphost names.

### About this task

If you do not already have an SNMP traphost configured to receive event notifications (SNMP traps), you must add one.

You can perform this task any time the cluster is running by entering the commands on the ONTAP command line.

### Step

1. If your environment does not already have an SNMP traphost configured to receive event notifications, add one:

```
system snmp traphost add -peer-address snmp_traphost_name
```

All event notifications that are supported by SNMP by default are forwarded to the SNMP traphost.

= Configure important EMS events to forward notifications to a webhook application

:icons: font

:relative\_path: ./error-messages/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./error-messages/..media/

You can configure ONTAP to forward important event notifications to a webhook application. The configuration steps needed depend on the level of security you choose.

== Prepare to configure EMS event forwarding

There are several concepts and requirements you should consider before configuring ONTAP to forward event notifications to a webhook application.

== Webhook application

You need a webhook application capable of receiving the ONTAP event notifications. A webhook is a user-defined callback routine that extends the capability of the remote application or server where it runs. Webhooks are called or activated by the client (in this case ONTAP) by sending an HTTP request to the destination URL. Specifically, ONTAP sends an HTTP POST request to the server hosting the webhook application along with the event notification details formatted in XML.

== Security options

There are several security options available depending on how the Transport Layer Security (TLS) protocol is used. The option you choose determines the required ONTAP configuration.

TLS is a cryptographic protocol that is widely used on the internet. It provides privacy as well as data integrity and authentication using one or more public key certificates. The certificates are issued by trusted certificate authorities.

## HTTP

You can use HTTP to transport the event notifications. With this configuration, the connection is not secure. The identities of the ONTAP client and webhook application are not verified. Further, the network traffic is not encrypted or protected. See [Configure a webhook destination to use HTTP](#) for the configuration details.

## HTTPS

For additional security, you can install a certificate at the server hosting the webhook routine. The HTTPS protocol is used by ONTAP to verify the identity of the webhook application server as well as by both parties to ensure the privacy and integrity of the network traffic. See [Configure a webhook destination to use HTTPS](#) for the configuration details.

## HTTPS with mutual authentication

You can further enhance the HTTPS security by installing a client certificate at the ONTAP system issuing the webhook requests. In addition to ONTAP verifying the identity of the webhook application server and protecting the network traffic, the webhook application verifies the identity of the ONTAP client. This two-way peer authentication is known as *Mutual TLS*. See [Configure a webhook destination to use HTTPS with mutual authentication](#) for the configuration details.

### Related information

- [The Transport Layer Security \(TLS\) Protocol Version 1.3](#)

## == Configure a webhook destination to use HTTP

You can configure ONTAP to forward event notifications to a webhook application using HTTP. This is the least secure option but the simplest to set up.

### Steps

1. Create a new destination `restapi-ems` to receive the events:

```
event notification destination create -name restapi-ems -rest-api-url
http://<webhook-application>
```

In the above command, you must use the **HTTP** scheme for the destination.

2. Create a notification linking the `important-events` filter with the `restapi-ems` destination:

```
event notification create -filter-name important-events -destinations
restapi-ems
```

## == Configure a webhook destination to use HTTPS

You can configure ONTAP to forward event notifications to a webhook application using HTTPS. ONTAP uses the server certificate to confirm the identity of the webhook application as well as secure the network traffic.

### Before you begin

- Generate a private key and certificate for the webhook application server
- Have the root certificate available to install in ONTAP

### Steps

1. Install the appropriate server private key and certificates at the server hosting your webhook application. The specific configuration steps are dependent on the server.

2. Install the server root certificate in ONTAP:

```
security certificate install -type server-ca
```

The command will ask for the certificate.

3. Create the `restapi-ems` destination to receive the events:

```
event notification destination create -name restapi-ems -rest-api-url
https://<webhook-application>
```

In the above command, you must use the **HTTPS** scheme for the destination.

4. Create the notification that links the `important-events` filter with the new `restapi-ems` destination:

```
event notification create -filter-name important-events -destinations
restapi-ems
```

**== Configure a webhook destination to use HTTPS with mutual authentication**

You can configure ONTAP to forward event notifications to a webhook application using HTTPS with mutual authentication. With this configuration there are two certificates. ONTAP uses the server certificate to confirm the identity of the webhook application and secure the network traffic. In addition, the application hosting the webhook uses the client certificate to confirm the identity of the ONTAP client.

### Before you begin

You must do the following before configuring ONTAP:

- Generate a private key and certificate for the webhook application server
- Have the root certificate available to install in ONTAP
- Generate a private key and certificate for the ONTAP client

### Steps

1. Perform the first two steps in the task [Configure a webhook destination to use HTTPS](#) to install the server certificate so that ONTAP can verify the identity of the server.
2. Install the appropriate root and intermediate certificates at the webhook application to validate the client certificate.
3. Install the client certificate in ONTAP:

```
security certificate install -type client
```

The command will ask for the private key and certificate.

4. Create the `restapi-ems` destination to receive the events:

```
event notification destination create -name restapi-ems -rest-api-url
https://<webhook-application> -certificate-authority <issuer of the client
certificate> -certificate-serial <serial of the client certificate>
```

In the above command, you must use the **HTTPS** scheme for destination.

5. Create the notification that links the `important-events` filter with the new `restapi-ems` destination:

```
event notification create -filter-name important-events -destinations
restapi-ems
```

= Update deprecated EMS event mapping

= EMS event mapping models

:icons: font

:relative\_path: ./error-messages/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./error-messages./media/

Prior to ONTAP 9.0, EMS events could only be mapped to event destinations based on event name pattern matching. The ONTAP command sets (`event destination`, `event route`) that use this model continue to be available in the latest versions of ONTAP, but they have been deprecated starting with ONTAP 9.0.

Beginning with ONTAP 9.0, the best practice for ONTAP EMS event destination mapping is to use the more scalable event filter model in which pattern matching is done on multiple fields, using the `event filter`, `event notification`, and `event notification destination` command sets.

If your EMS mapping is configured using the deprecated commands, you should update your mapping to use the `event filter`, `event notification`, and `event notification destination` command sets.

There are two types of event destinations:

1. **System-generated destinations:** There are five system-generated event destinations (created by default)

- ° allevents
- ° asup
- ° criticals
- ° pager
- ° traphost

Some of the system-generated destinations are for special purpose. For example, the `asup` destination routes `callhome.*` events to the AutoSupport module in ONTAP to generate AutoSupport messages.

2. **User-created destinations:** These are manually created using the `event destination create` command.

```

cluster-1::event*> destination show

Hide
Name Mail Dest. SNMP Dest. Syslog Dest.
Params

allevents -
false
asup -
false
criticals -
false
pager -
false
traphost -
false
5 entries were displayed.
+
cluster-1::event*> destination create -name test -mail test@xyz.com
This command is deprecated. Use the "event filter", "event
notification destination" and "event notification" commands,
instead.
+
cluster-1::event*> destination show
+
Hide
Name Mail Dest. SNMP Dest. Syslog Dest.
Params

allevents -
false
asup -
false
criticals -
false
pager -
false
test test@xyz.com
false
traphost -
false
6 entries were displayed.

```

In the deprecated model, EMS events are individually mapped to a destination using the `event route add-destinations` command.

```
cluster-1::event> route add-destinations -message-name raid.aggr.*
-destinations test
This command is deprecated. Use the "event filter", "event notification
destination" and "event notification" commands, instead.
4 entries were acted on.

cluster-1::event> route show -message-name raid.aggr.*
 Freq
Time
Message Severity Destinations Threshd
Threshd

raid.aggr.autoGrow.abort NOTICE test 0
0
raid.aggr.autoGrow.success NOTICE test 0
0
raid.aggr.lock.conflict INFORMATIONAL test 0
0
raid.aggr.log.CP.count DEBUG test 0
0
4 entries were displayed.
```

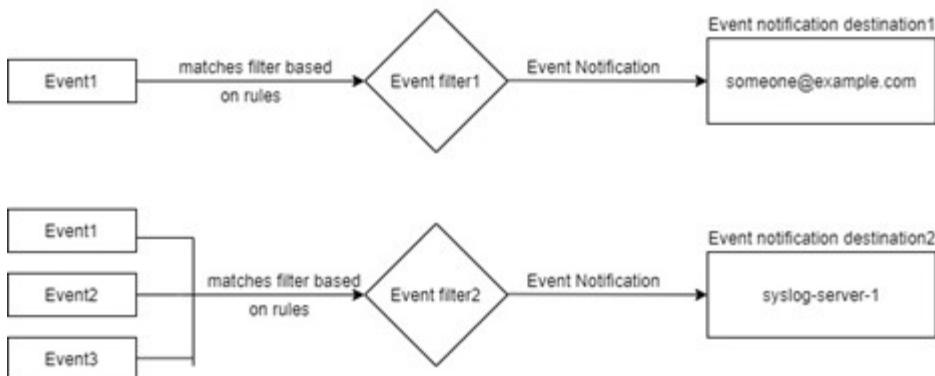

The new, more scalable EMS event notifications mechanism is based on event filters and event notification destinations. Refer to the following KB article for detailed information on the new event notification mechanism:

- [Overview of Event Management System for ONTAP 9](#)

### Legacy routing based model

### Event notification based model

= Update EMS event mapping from deprecated ONTAP commands

:icons: font

:relative\_path: ./error-messages/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source./error-messages/./media/

If your EMS event mapping is currently configured using the deprecated ONTAP command sets (event destination, event route), you should follow this procedure to update your mapping to use the event filter, event notification, and event notification destination command sets.

### Steps

1. List all the event destinations in the system using the `event destination show` command.

```

cluster-1::event*> destination show

Hide
Name Mail Dest. SNMP Dest. Syslog Dest.
Params

allevents -
false
asup -
false
criticals -
false
pager -
false
test test@xyz.com -
false
traphost -
false
6 entries were displayed.

```

- For each destination, list the events being mapped to it using the `event route show -destinations <destination name>` command.

```

cluster-1::event*> route show -destinations test
 Freq
Time
Message Severity Destinations
Threshd Threshd

0
raid.aggr.autoGrow.success NOTICE test 0
0
raid.aggr.lock.conflict INFORMATIONAL test 0
0
raid.aggr.log.CP.count DEBUG test 0
0
4 entries were displayed.

```

- Create a corresponding event filter which includes all these subsets of events. For example, if you want to include only the `raid.aggr.*` events, use a wildcard for the `message-name` parameter when creating the filter. You can also create filters for single events.

You can create up to 50 event filters.

```
cluster-1::event*> filter create -filter-name test_events

cluster-1::event*> filter rule add -filter-name test_events -type
include -message-name raid.aggr./*

cluster-1::event*> filter show -filter-name test_events
Filter Name Rule Rule Message Name SNMP Trap Type
Severity
Position Type

test_events
 1 include raid.aggr.* *
*
 2 exclude * *
*
2 entries were displayed.
```

4. Create an event notification destination for each of the event destination endpoints (i.e., SMTP/SNMP/syslog)

```
cluster-1::event*> notification destination create -name dest1
-email test@xyz.com

cluster-1::event*> notification destination show
Name Type Destination

dest1 email test@xyz.com (via "localhost" from
"admin@localhost", configured in "event config")
snmp-traphost snmp - (from "system snmp traphost")
2 entries were displayed.
```

5. Create an event notification by mapping the event filter to the event notification destination.

```

cluster-1::event*> notification create -filter-name asup_events
-destinations dest1

cluster-1::event*> notification show
ID Filter Name Destinations
----- -----
1 default-trap-events snmp-traphost
2 asup_events dest1
2 entries were displayed.

```

6. Repeat steps 1-5 for each event destination that has an event route mapping.

Events routed to SNMP destinations should be mapped to the snmp-traphost event notification destination. The SNMP traphost destination uses the system configured SNMP traphost.

```

cluster-1::event*> system snmp traphost add 10.234.166.135

cluster-1::event*> system snmp traphost show
 scspr2410142014.gdl.englab.netapp.com
(scsp2410142014.gdl.englab.netapp.com) <10.234.166.135>
Community: public

cluster-1::event*> notification destination show -name snmp-traphost

 Destination Name: snmp-traphost
 Type of Destination: snmp
 Destination: 10.234.166.135 (from "system snmp
traphost")

= ONTAP command reference

:icons: font

:relative\_path: ./concepts/

:imagesdir: /tmp/d20230517-16854-12t6yg9/source//error-messages/../media/

:hardbreaks:

For each major ONTAP release, the commonly available CLI commands (ONTAP manual pages, or man pages) are bundled into a *command reference*. These command references explain how to use the CLI commands in each ONTAP release. Man pages are also available at the ONTAP command line with the `man` command.

== Command references for supported versions of ONTAP
